conditions, proportional valves close, and let air-conditioning circulating backwater first directly to exchange heat with the water of the pump units.

2.2 The solar hot water system

The solar hot water system is a semi-centralized system which adopts concentrated collecting heat, household heat storage and auxiliary heating. The system includes three parts.

- The mess hall system: it comprises 24-m^2 solar collector panels on the facade. These panels supply heat to two tanks, each of which has a capacity of 450 l.
- The east system: it comprises 57.6-m^2 solar collector panels distributed in two rows over the roof. These panels supply heat to three tanks, two with a capacity of 340 l located on fifth and fourth floors and one with a capacity of 270 l situated on the third floor. After auxiliary heating by electricity power in the water heater, the boiling drink water is supplied to satisfy the needs in the public offices. The heated water is also supplied for heating of temperature aging workshop on the third floor.
- The west system: it comprises 28.8-m^2 solar collector panel distributed in one row over the roof. This panel supplies heat to two water tanks, with a capacity of 450 l. Water in the tanks is supplied for washing hand purposes in the public toilets.

2.3 The natural lighting system

The natural lighting system is constituted by an integrated system composed of solar collector panels, solar photovoltaic (PV) panels and glass curtain walls. All four rows shown in Figure 5 comprise the integrated system installed with the same inclination angle.

This configuration integrates the solar energy systems in the building envelope and allows three different functions:

- Three rows of solar collector panels preheat water for workers. These rows are divided into two solar hot water systems unequally: one system is connected with 57.6 m^2 collector panels and the other with 28.8 m^2 panels.
- The PV panels provide power for office lighting and supply energy to the billboard lighting outside the building.
- The curtain walls contribute to light the fifth floor and allow for saving a considerable amount of energy otherwise necessary for lighting.

3 ENERGY-SAVING RESULTS FOR THE MULTI-INTEGRATED SYSTEM

The integration of renewable energy in this building is obtained by three systems, i.e. solar-ground source energy system, solar

PERPUSTAKAAN NASIONAL REPUBLIK INDONESIA

Downloaded from http://academic.oup.com/ijlct/article/7/3/192/759000 by guest on 24 March 2023

hot water system and the natural lighting system. The required data for the calculation are taken from calorimeters and electricity meters. These are controlled through the building automation system (BAS) of the building which works with a direct digital control (DDC) system. This section considers mainly on the energy-saving effects resulting from solar and ground energies.

3.1 Energy-saving effect of solar-ground source heat pump system

This section analyses the energy-saving effects related to the integration of solar energy and ground heat energy. The heat pump system power load and the evaluation of system's coefficient of performance (COP) are shown in Table 1.

As shown in Table 1, the heat pump itself has a COP of 4.6. When taking the power loads of the ground circulation pump and the heating water supply pump into consideration, the overall COP reduced to 3.6. In this paper, the operational effect was analyzed by comparing the ground source with a traditional air-source pump system in the same operating conditions in heating. This comparison methodology has already been adopted in literature [14].

Obviously, the operating parameters of the heat pump change along with the external environmental temperatures. Table 2 shows the relationships between some operating parameters and the environmental temperature [15].

Two periods were selected to analyze the system performance, a 'working period' from 19 to 31 January 2011, and the 'Spring Festival holiday period' from 31 January to 12 February 2011. Heat supply data for those two periods are reported in Table 3. The data under the category of 'Heat supply' were the actual heat supply value for the whole heating season (120 days in Beijing). This was estimated along with the 108-day working period and the 12-day off period, referenced to the specific working day load and off day load shown by the data obtained from the BAS.

Table 1. *Heat pump system power load [kW] and the evaluation of the overall system COP*

Model	Heat pump unit		Water pumps		Overall COP
	Qload	COP	Ground	Supply	
PSRHH1501	637.6	4.6	20	20	3.6

Table 2. *Relationships between operating parameters and environmental temperatures*

Selected season	Relationship of cooling/heating power and environmental temperature	Relationship of power consumption and environmental temperature
Summer	$W = -0.76 \times t + 88$ (kW)	$N = 0.21 \times t + 13.15$ (kW)
Winter	$W = 2.15 \times t + 52.2$ (kW)	$N = 0.25 \times t + 17.28$ (kW)

Figure 6 shows the temperature obtained from the data acquisition system in the period from 08:19 of 25 January 2011 to 07:19 of 26 January 2011.

A comparison has been made on the heating performance between a ground-source and an air-source heat pump. According to the Chinese National Standard [15] and environmental conditions of Beijing, the average COP of the screw-type air-source heat pump units in winter equals to 2.64. The average heating capacity in normal working period in the heating season was 414.6 kW (Table 3; 59 703 kW/(12 × 12) = 414.16 kW, the first '12' stands for the length of selected normal working days and the second '12' represents the 12 h' operating time per day). Based on this, we then compare normal heating days in general (Table 4). Despite the different COPs, the air-source unit also needs extra power to defrost, which account for ~10.2% of the total energy consumption [12]. Combining those two aspects, the actual power input needed in the air-source system equals to 174.89 kW. Compared with the 115.17 kW of the ground-source system,

Table 3. *Energy consumption of heating in working and festival periods*

Period	Working period	Festival period
Energy reading at the beginning (kWh)	231 327.0	291 030.0
Energy reading at the end (kWh)	291 030.0	308 474.0
Energy consumption in the period (kWh)	59 703	17 444
Heating area (m^2)	12 581.5	
Heat supply (kWh/m^2)	44.1	
Heat corresponding to coal (kg/m^2)	14.7	

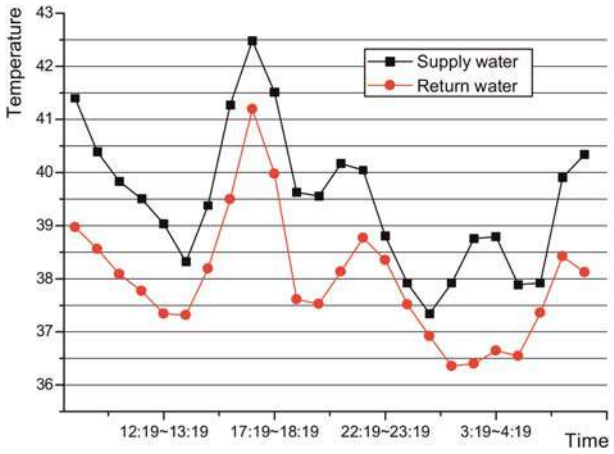

Figure 6. *Supplied and returned water temperature recorded in a 24 h operation.*

Table 4. *Power consumption comparison between the ground-source heat pump and the air-source heat pump*

Type of heat pump	Heating capacity (kW)	COP	Power input (kW)
Ground source	414.6	3.6	115.17
Air source	414.6	2.64	157.05

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

the ground-source heat pump is ~34.1% more efficient than the air-source heat pump in heating operation in a normal working period. Moreover, the integration of solar and ground sources in this building provides a stable operating performance in comparison to a normal ground-source heat pump system.

3.2 Energy-saving effect of solar collector panels

The measured data through the solar calorimeters are used to analyze the energy-saving effects of solar collector panels. The exact calculation is shown in Table 5 for the period from 19 January to 12 February 2011. In this table, the daily CO_2 emission reduction is calculated by assuming the efficiency of power-to-heat as 90%.

3.3 Energy-saving effect of solar hot water system

This analysis primarily focuses on hot water needed for drinking. There are ~400 people working in this building, so considering a request of 2 l for each person to drink everyday, the total hot water needed is ~800 l every day. Considering the average water temperature heated by collectors to be 50°C, and average underground water temperature to be 15°C in Beijing, the solar hot water system can save up to 41%. It is assumed by comparing the energy consumed from 100 to 50°C and from 100 to 15°C, because in traditional non-low-carbon offices, this energy may totally come from electrical energy.

Table 6 shows the actual electricity consumed by water heater systems from 1 July to 12 July. It is shown that the average electricity consumed for auxiliary heating is 11.07 kWh, so the electrical energy saved is ~7.7 kWh each day (41% saving), which equals to 3.8-kg CO_2 emission reduction every day.

Table 5. *Calculation of energy-saving effect of solar collector panels*

Items	Acquired heat energy (kWh)	Daily acquired heat energy (kWh/day)	Daily CO_2 emission reduction (kg/day)
Solar panels for the mess hall	497	20.70	18.80
Solar panels for the system of west	677	28.20	25.61
Solar panels for the system of east	1000	41.67	38.00
Solar panels for the heat pump system	1573	65.54	59.77
Total effect for all the solar panels	3747	156.11	142.37

Table 6. *Actual electricity used in the water heater systems*

Floor	Meter reading at the beginning (kWh)	Meter reading at the end (kWh)	Total electric power (kWh)
Fourth	1813.55	1883.28	69.73
Fifth	4367.37	4563.32	195.95

4 ADVICE FOR INTEGRATED SYSTEMS

On the basis of the analysis of the three portions of the multi-integrated renewable energy system, some advice is reported below to help the processes of design, operation and inspection of such systems in other buildings.

4.1 Advice on design

Regarding the system described in this paper, design advice regards the following aspects:

- In the solar-ground source heat pump system, use high-efficiency solar panels and the size of the circulating pump should be properly chosen to avoid additional energy consumption. For example, during the test run, it can be detected that the temperature of the inlet water in the panels is ~45°C, which increases the difference between the inlet water and the ambient environment, thus lower the collecting efficiency. This results from the unmatch between the area of collector panels and the usage of heated water. After reforming the water to a new system in the mess hall, the situation is improved and the panels are used more properly.
- The solar and ground sources can be connected in series with water first going through the collector tank (connection with the heat pump on the condenser side) or going through the underground pipes (connection with the heat pump on the evaporator side), or can be connected in parallel. Figure 7 shows the last two configurations. Obviously, the performance of each system changes along with the temperature of inlet water. The connection in parallel is

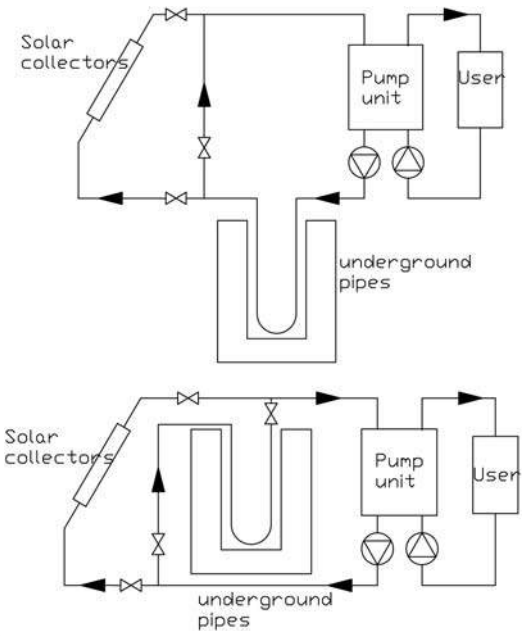

Figure 7. *The solar and ground heat source connected in series with connection on the evaporator side of the heat pump (above) and connected in parallel (below).*

PERPUSTAKAAN NASIONAL REPUBLIK INDONESIA

generally more complex from a constructive point of view, but it guarantees the highest COP of the heat pump as the temperature difference with the external environmental temperature is the lowest.

- The natural lighting system regards the choices of the glass-roof, as this can provoke an unwanted increase in the indoor temperature. Windows and glass curtain wall should be installed with an appropriate angle. Moreover, a limited heating accumulation in the circulating water is suggested. For instance, in this system, the running circulating water inside the panels on the natural lighting roof and the angled installation can keep the top of roof a modest temperature in hot summer days, and reduce the greenhouse effect slightly.

4.2 Advice on operation and inspection

A multi-integrated renewable energy system needs a careful and complete inspection before normal working period, in order to test and control every district of the system properly. Regarding the solar-ground source heat pump system, there are four main parts of inspection: the power input and heating/cooling supply system, the ground temperature field in the ground heat exchanger installed area, the heat pump system and the solar units [16, 17]. Coherently with this,

- To achieve a sustainable energy saving operation, it is required to keep the ground heat flow balanced and to monitor the heat pump operating conditions closely. An unbalance of soil temperature can generate heat accumulation or cold accumulation. For example, for a cooling system, heat accumulation on the soil gives a COP drop of 2.5% every °C of accumulation. In Eastern China area, there is an unbalanced exchange with a 2 °C rise of the temperature over one year period. Reversely, a cold accumulation of 4°C has been registered in Germany with a drop of COP of 4.1% every °C. Moreover, in the case of large systems of ground-source heat pipes, care must be taken regarding the formation of heat barrier, with peripheral pipes which influences interior ones.
- During the inspection of automatic or manual-controlled function of the heat pump system, the basis of change function should be selected and well defined as needed. It means applying influent factor of outside environment weather. In this control system, it detects the temperature and contents of CO_2 in lawn of square in front of this building. These are essential in the defined parameters of DDC inside.

5 CONCLUSIONS

The necessity to integrate several renewable energy sources in buildings has been the starting point of this paper. In fact, international statistics and agreements show the necessity to increase the diffusion of sustainable technologies and buildings, especially in transition economies. A newly built office building was used for this case study, which helps discussing the status of renewable energy systems in China, focusing in particular on the integration of solar and geothermal energy systems.

After analysis of energy-saving effects of the solar-ground source heat pump system and the comparison with an equivalent air-source heat pump system, the paper has considered the collector panels, the water heater system and the natural lighting system. Results have shown that the energy consumption in the ground-source system is 34.1% more efficient than that of the air-source system in a normal working system in Winter, 174.89 kW of the air-source system compared with 115.17 kW of the ground-source system. The saving is given by the different COPs and extra energy consumption for defrosting in an air-source system. Moreover, the solar collector panels in the system are estimated to contribute 156.11 kWh per day saving for heating in the workshop and for cleaning in the mess hall, and it equals 142.37 kg reduction of CO_2 emission per day. The solar hot water system contributes a 47% power saving in supplying drinking water. In conjunction with a detailed observation and research into their actual operation, the paper has given some advice for the process of design, operation and inspection. The hope is that the analysis of the real integrated system in this office building could be useful for the development and integration of renewable energy systems in other low-carbon buildings in China.

Abstract: This paper examines the economic and environmental impacts of district cooling systems (DCS) that are integrated with renewable energy sources and thermal energy storage (TES). Typically, a DCS offers a highly efficient and environmentally friendly alternative to traditional air conditioning systems, providing cool air to buildings and communities through a centralized system that uses chilled water. However, the integration of renewable energy and thermal energy storage into these systems can further increase their sustainability and efficiency, reducing their dependence on fossil fuels and improving their ability to handle fluctuations in demand. The goal of this paper is to provide a comprehensive review of the current state of the art of renewable energy-driven DCS with TES integrated and to highlight the benefits and challenges associated with these systems. Finally, the findings of this paper offer valuable insights into the potential for renewable energy-powered district cooling systems to contribute to a more sustainable and efficient built environment.

1. Introduction

Energy and the environment are considered two concurrent emerging global challenges today. This has led to increasing global commitment at all levels considering global warming and climate change, which is resulting in an irreversible impact across the globe. The environment is threatened by the influx of greenhouse gases (GHG), particularly CO_2-heightened radiation and heat sourced from fossil fuel combustion. Studies have shown that CO_2 is the major contributor to GHG emanating from rising heat waves and long-wave infrared radiation from the earth's surface [1,2]. The quest for better economic advantage and environmentally friendly cooling systems ignited the interest in exploring less energy consuming and high-performing district cooling systems (DCS) [3]. It has been established that approximately 17% of the total electricity generated is consumed by refrigeration applications and this inevitably led approximately 8% of total greenhouse gas (GHG) emissions to the environment. DCS technology has a direct impact on global warming, considering the rising heat waves heightened by greater energy consumption by the DCS. In response, renewable energy-powered cooling systems and thermal energy storage incorporated with vacuum centrifugal chillers (VCCs) were used as plausible options with high proficiency in terms of energy savings and minimal environmental impacts [4].

However, the generation and consumption of electricity for both domestic and industrial purposes contributed immensely to the rising heat waves in the environment. Consequently, this raises a lot of worry about the intensive energy demand in buildings considering accelerated consumption for comfort-driven purposes worldwide. On this note, substantial growth in energy consumption was recorded, by 20 to 40%, for domestic and commercial apartments in most advanced countries [5]. For instance, approximately 36%

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

of CO_2 emissions from Europe is from energy consumption by residential and commercial buildings, accounting for 40% of the output of the entire energy system [6]. Similarly, in Asia, approximately 35% of buildings consumed the total energy generated and a significant proportion of this energy is consumed for cooling and heating purposes across different parts of China [7]. In the same vein, 38.9% and 33% of the total energy consumed is utilized by the residential building sector in the United State of America (USA) and the United Arab Emirates (UAE), respectively [8]. Therefore, the negative impact of climate change can be slowed down through compromises in comfort, i.e., by reducing electricity consumption for heating and cooling. In this context, conventional standalone chiller plants installed in individual buildings, or industrial or commercial facilities were overworked. This led to the deployment of a district cooling system (DCS) that will contribute immensely to the significant energy reduction target and upscale maximum system efficiency. Figure 1 shows the common methods of heat production and energy sources linked to the technology period of the DCS.

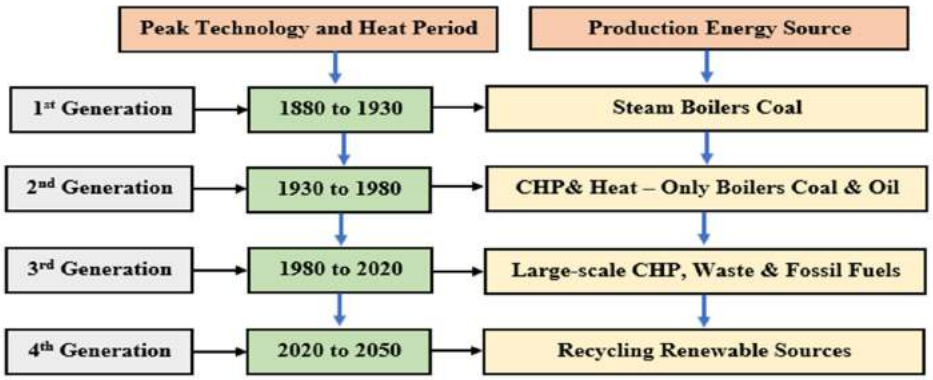

Figure 1. Production and energy sources for DCS.

In support of this claim, a DCS offers advantages such as a lower energy demand compared to on-site cooling systems (conventional), due to large-scale central water-cooled chiller plants for a given cooling system, efficient and flexible capacity, peak-period saving potential, a lower unit cost of cooling, low maintenance and cost-effectiveness, reduced environmental emissions, etc. [9]. Further, the technology would reduce damages linked to transmission, enhance productivity conversion, support the integration of other technologies, and foster sustainability and economic viability [8,9]. As a contemporary developed technology, DCS are used in areas flooded with high-density buildings due to their high cooling efficiency. Moreover, the technology is used to supply energy for space cooling and dehumidification [10,11]. DCS are tailored towards meeting and satisfying the energy demand for cooling purposes for an energy distribution network within a confined marketplace [12,13]. A DCS involves decentralization and centralization, where the former is more suitable for large-scale regions. Energy transformation occurs in diverse buildings. However, a moderately small capacity building is preferred, where advanced energy technologies are assembled outside the building for convenient energy flow in the direction of the building through the DCS network [13–15].

However, more cooling systems are being heavily used as we adapt to hot climatic conditions experienced in many countries on the one hand, and more heating systems are being equally engaged in colder zones. As a result of this heavy load, the conventional DCS is incapable of meeting and sustaining the changes in today's society that are often circumscribed by high energy consumption [16–18]. This compelled the integration of TES tanks with VCC systems in DCS plants [19,20], and the integration of renewable energy resources into DCS [2] to boost the efficiency of the process and improve the economic gains of the process. Consequently, the integration of renewable energy resources into DCS has taken center stage in the research in this field in recent decades. With this development, renewable energy sources such as biomass, wind, solar, and geothermal energy were

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

identified as the most feasible technologies for DCS integration [12,15]. Nevertheless, issues linked to global warming and climate change are posing challenges to economic growth due to the limitations associated with fossil-based energy [20–22]. As a result, a hike in electricity bills and the possibility of fossil fuel exhaustion has led to revisiting the utilization of renewable energy sources to power cooling/heating systems [18,22]. The use of renewable energy will serve multiple benefits such as supporting energy security missions, decreasing the rate of GHG emissions, and ensuring dependable and affordable energy delivery [23]. Surprisingly, despite the above-mentioned advantages, reviews addressing the sustainability, economic and environmental benefits of DCS powered by the grid, renewable energy technologies integrated into DCS and thermal energy storage (TES) with VCCs incorporated are still lacking. Therefore, the objective of this work is to review the current state of the art of renewable energy-driven DCS with TES, examine the benefits and challenges associated with integrating renewable energy and thermal energy storage into DCS, and compare the performance of renewable energy-driven DCS with TES to traditional air conditioning systems. Moreover, this review also presents recommendations for the future development and implementation of renewable energy-powered DCS with TES and concludes by highlighting the potential for these systems to contribute to a more sustainable and efficient built environment.

2. District Cooling System (DCS)

A DCS is a centralized cooling system that provides cooling services to multiple buildings or facilities within a defined geographic area, such as a district, campus, or city. It is an energy-efficient alternative to individual cooling systems for each building, as it eliminates the need for each building to have its own cooling system [20]. DCS offers several advantages over traditional cooling systems, including higher energy efficiency, lower maintenance costs, and reduced environmental impact. It is particularly suitable for large commercial or residential developments, where a high demand for cooling is required [21]. As shown in Figure 2, the DCS comprises a cooling source, chillers, a distribution network, heat exchangers, and customer installations (buildings) [22]. In hot countries, for instance, high electricity consumption and resulting carbon emissions are two main concurrent challenges of the cooling sector. Similarly, countries located near the tropics, also known as the Gulf Cooperation Council (GCC) comprising Saudi Arabia, Kuwait, Bahrain, Oman, Qatar, and the United Arab Emirates, are known to be among the hottest with high climate changes [23,24]. Their electricity consumption is approximately 70% maximum with a minimum of 50% due to the air conditioning system in the GCC. It was projected that the cooling demand in this region will triple by 2030 compared to in 2010. However, the amount of electricity consumed in households, mainly for air conditioning, was recorded as 70%, 60%, and 36% in the Kingdom of Saudi Arabia, Oman, and the United Arab Emirates, respectively [25–28]. There is a similar scenario in Malaysia, where the air condition system is also considered to consume among highest amount of energy, accounting for 28 to 46% of the total electricity consumption [29]. Overall, it can be established that electrical power generation expansion needs to increase by approximately 60% to meet the air cooling sector's energy requirements [24].

Typically, in DCS plants, the need for each building to have its cooling production system is avoided through centralization of the supply from the plant. This minimizes high capital, and operational costs and affords ease of maintenance [30]. However, the management and distribution of chilled water to various end users have channeled a network monitored by a third party [31]. The higher efficiencies of the DCS through the utilization of centralized energy production plants led to a reduction in GHG emissions compared to the conventional system [32]. Therefore, in a bid to enhance the efficiency of DCSs in cooling technology, the incorporation of a TES tank with a chiller system and renewable energy integration were introduced. This allows for increased operational flexibility and enhances the optimization of the technology [33,34]. In this work, various renewable energy integration methods as well as the incorporation of TES with VCCs into DCS are discussed

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

in Sections 3, 3.1–3.5, 4, 4.1 and 4.2, respectively. The various environmental and economic benefits as well as the sustainability status of the two technologies are discussed. Moreover, the various contributions in terms of environmental, economic, and energy savings of the technologies under review are highlighted in Section 3.

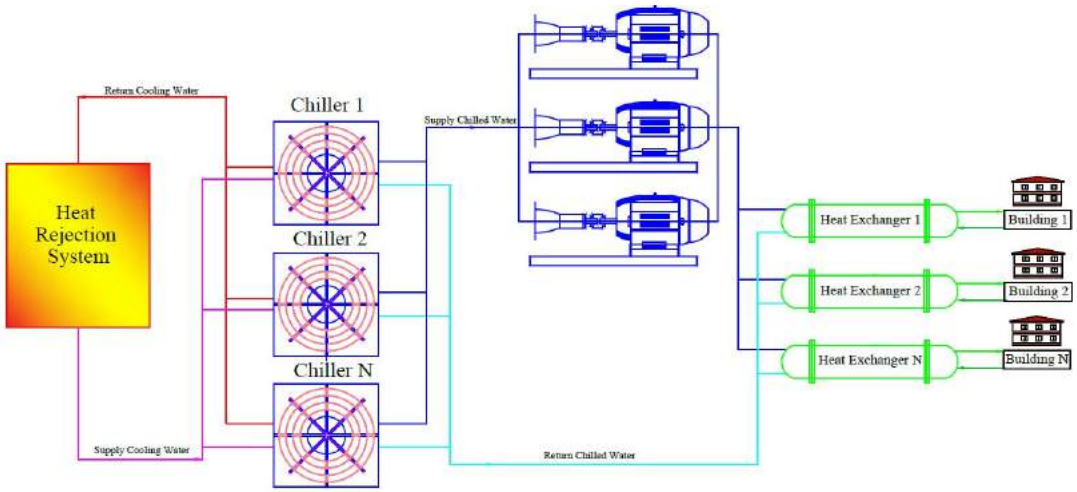

Figure 2. A schematic network of a typical DCS.

Types of District Cooling Systems

There are several types of district cooling systems, namely centralized DCSs which are large-scale systems that provide cooling to multiple buildings through a network of pipelines connected to a central cooling plant; decentralized DCSs that are small-scale systems that provide cooling to a single building or a limited number of buildings through a cooling plant [35]; hybrid DCS that are often a combination of centralized and decentralized systems, where cooling is provided through a combination of a central cooling plants and individual cooling units within the buildings; absorption chiller-based DCS use absorption chillers that are powered by waste heat or renewable energy sources to provide cooling [36]; chilled-water DCS are used as central cooling plants to generate chilled water that is then distributed to multiple buildings through a network of pipelines; direct-expansion DCS uses refrigerants to provide cooling, and the refrigerant is directly circulated through the building's air conditioning systems [37]. Table 1 presents the benefits and challenges of the various types of DCS.

Table 1. Benefits and challenges of different types of district cooling systems.

DCS Type	Benefits	Challenges	Reference
Centralized DCS	Improved air quality, high energy efficiency, reduced carbon footprint, and high initial investment.	Long-term maintenance costs and complex infrastructure.	[38]
Decentralized DCS	Flexibility to adapt to changing demand, lower initial investment, and lower maintenance costs.	Lower energy efficiency, higher energy consumption and costs, and limited cooling capacity.	[39]
Hybrid DCS	Combines the benefits of both centralized and decentralized systems and lowers energy consumption and costs.	Long-term maintenance costs and complex infrastructure.	[40]
Absorption chiller-based DCS	High energy efficiency, and reduced energy consumption and costs.	Dependence on waste heat or renewable energy sources and complex technology.	[41]

PERPUSTAKAAN NASIONAL

Table 1. *Cont.*

DCS Type	Benefits	Challenges	Reference
Chilled-water DCS	Reduced energy consumption and costs; reduced carbon footprint and high energy efficiency.	The high initial investment, complex infrastructure, and long-term maintenance costs.	[37]
Direct-expansion DCS	High energy efficiency, reduced energy consumption and costs, improved air quality, and minimized carbon footprint.	The high initial investment, complex infrastructure, and highly dependent on refrigerants and cooling fluids.	[42]

3. Renewable Energy Integration into DCS

The basis of scientific principles for the creation of a balance between the environment, energy, and sustainable power consumption lies within sustainable development requirements and resource utilization mechanisms, which are among the pivotal issues in today's modern society for economic and social development [43]. In this context, the irreversible increase in energy demand tied with ever-growing GHG emissions prompted the need for clean sustainable energy to relieve the crisis of high energy consumption and rising heat waves [44]. Therefore, the incessant liberation of GHG can be largely controlled with the integration of indigenous renewable energy resources into the DCS [45]. Accordingly, various co-renewable energy integration methods into the DCS are discussed.

3.1. The Use of Biomass Energy in DCS

The indiscriminate discharge of GHG emissions owing to excessive fossil fuel consumption aggravated the increasing climate change across the globe [26,27]. Therefore, energy from biomass is considered among the attractive alternative sources of renewable energy that are proficient and capable of fulfilling the ever-growing energy demand [28,29]. Biomass contributed up to 14% of the worldwide renewable energy consumed, with approximately 90% utilized in rural areas [30–32]. Biomass is a type of renewable derived from organic materials (plant or animal) that produce energy after burning. For instance, biomass is sourced from forest-based, agriculture biomass, and waste-based feedstocks [33–37]. During photosynthesis, solar energy is stored in biomass. Of the 2×10^{12} energy stored during photosynthesis, only 0.5% by weight is used as a crop for food for humans. Biomass is processed to improve its quality for energy generation and to reduce pollution [38–51]. Techniques such as pyrolysis, Fischer–Tropsch synthesis, synthetic natural gas production, and torrefaction are used for this. Energy generation from processed biomass is an active area of research and optimization, with a structured review by Masoud et al. [52], incorporating thermal storage. Designing and optimizing biomass-based systems are challenging due to factors such as moisture content, working fluid, operating cycle, char and tar production, and gas-to-biomass ratios [53]. Research on biomass processing and energy conversion is being carried out from various angles to make biomass-based systems more affordable and reliable. To achieve this, many aspects such as cost and technology, as well as chemical, thermodynamic, and environmental factors, need to be considered. Ahmadi et al. [54] studied the impact of energy and energy efficiency on the cost and CO_2 emissions of biomass-fueled energy systems using a thermodynamic model. Moharamian et al. [55] compared three configurations of a mixed biomass–natural gas energy system in terms of technology and economics and evaluated the sensitivity of the hybrid systems in an organic Rankin cycle setting, with changes in energy generation pathways. Studies have shown that lower amounts of CO_2 and carbon monoxide are emitted from biomass combustion compared to burning fossils. This CO_2 can be reused after the biomass is burned, thus making it carbon neutral [56,57]. Thermochemical and biochemical processes are two options for converting stored energy in biomass and the choice of which is tied to a particular type of application [58]. The applicability of using biomass energy in a DCS is such that the heat generated by the utilization of the biomass is used to cool the absorption chiller. Subsequently, insulated pipelines are used for the

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

circulation of the cooled air into different parts of the building facility and are often maintained at a particular temperature throughout the process.

Therefore, one potential substitute for conventional air-cooling systems is liquid cooling, which involves transferring heat away from a computer or electronic device using a liquid, typically water, rather than air. In a liquid cooling system, water is pumped through a closed loop system that includes a water block, which is a heat sink that is in contact with the electronic device generating heat. As the water flows through the water block, it absorbs heat and carries it away from the device. The heated water then flows through a radiator, where the heat is dissipated into the air, and the cooled water is pumped back into the water block to repeat the cycle [4,11]. This approach offers solution-based modules such as a GHG reduction strategy, energy saving, and sustainable energy supply in this integrated system [59]. Other applications of biomass-based cooling systems can provide heat or steam for industrial processes such as paper or pulp production, or heating and hot water needs in buildings through direct means or a thermal network in district heating systems. The combination of biomass with other fuels in big power plants is becoming more prevalent due to improved efficiency. The term "co-firing" in the biomass industry has different interpretations. In the energy sector, it refers to the simultaneous production of various forms of energy, whereas in biomass-powered systems, it means blending biomass with fossil fuels (usually coal or natural gas) to partially replace fossil fuels [60]. Further, waste derived from biomass incineration is used to power absorption chillers; in this way, the waste is judiciously transformed into value-added products rather than ending in landfills. Moreover, this process saves energy consumption by 60% and decreases the CO_2 emissions rate per unit of cooling compared to other conventional compression chillers [61]. Rentizelas et al. [62] proposed the development of an increased biomass supply chain for possible use in DCS. According to the authors, the development offers advantages such as cost savings and efficiency, and reduces warehouse effects [62].

3.2. The Use of Solar Thermal Energy in DCS

The increase in energy consumption worldwide is expected to raise CO_2 emissions by 60% by the end of 2030 [63,64]. The compelling internal cooling demands, particularly during winter seasons for mainly thermal comfort, are said to be the reason behind this [65]. This has led to the overwhelming response by scientists worldwide towards the exploration of abundant solar energy, which is known to be readily available all year round on most of planet earth [66]. Applications of high solar energy radiation in DCS, domestic cooking wares, water heating, electricity generation, and refrigeration are foreseeable with multiple benefits [67]. Therefore, installation of thermally driven cooling machines using solar energy will support meeting the cooling demands experienced during the hot season/period. Most importantly, this cooling system offers improved efficiency in terms of energy consumption and minimizes environmental consequences as compared to vapor compression machines [68]. Thus, climate change mitigation and an energy-balanced target would considerably upscale the contribution of solar energy. In this way, the cooling demand experienced during the hot season can be substantially addressed using the supplied energy obtained from solar thermal (ST) technologies [2]. Moreover, ST energy can potentially replace fossil fuels and complement the energy needed for hot water and cooling inside buildings.

Therefore, ST-driven DCS consist of solar thermal collectors connected to thermally driven chillers for space cooling in buildings [69]. ST technology is also known as green cooling technology and works based on the principle of converting solar radiation into heat energy [70]. Hence, thermally driven absorption chiller machines are used to generate heat energy required for cooling using this technology. Installation of ST technology is increasing due the ease and efficiency of the cooling process [71]. Further, thermally activated absorption chiller machines for cooling are regarded as environmentally friendly owing to zero GHG emission with no effect on the ecosystem. As such, ST-integrated DCS are being considered for commercial use [67]. Additionally, ST collectors can be

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

used to supply DCS absorption chillers with low thermal heat requirements. Therefore, ST energy-driven DCS are attractive alternatives in countries with low local supply of fossil fuels.

3.3. The Use of Geothermal Energy in DCS

Geothermal energy is a thermal form of energy found in the earth's crust, formed because of the formation planet and the radioactive decay of materials. This form of energy is derived from the earth's central core at a depth of 6437.376 km from the earth's outer surface. However, the high temperature on the earth's central surface is mainly due to the decay of radioactive particles [2]. Geothermal energy is renewable and obtained from within the earth, used directly for heating and electricity generation. Geothermal energy is considered different from other renewables due to year-long availability and use at any time of the day. Moreover, this form of energy contributes substantially to safeguarding the atmosphere and preserving public health from risks emanating from emissions of burning fossils [46]. A natural temperature gradient from higher to lower sources normally exists based on the second law of thermodynamics. Thus, heat moves towards the outer surface of the earth with approximately 42 million thermal megawatts. However, in a geological process also known as plate tectonics, some of this thermal heat is reserved at temperatures and depths for commercial applications [2].

Typically, in geothermal reservoirs, water is used as the most common fluid for heat transfer. Additionally, geothermal reservoirs for power production use a direct heating system with low and medium temperatures [72]. Some of the merits of this process include the relative abundance, zero competition for land requirements, fewer atmospheric pollutants, and that it is completely independent of weather conditions, making it more viable compared to other renewable technologies [73]. Moreover, proven sustainability, low cost, and cleanliness are some of the advantages that set the bar higher for using geothermal energy in DCS. This has ignited interest in the growing use of geothermal energy [74].

3.4. The Use of Solar Photovoltaic Systems in DCS

Solar photovoltaic systems have been opted as a non-polluting and sustainable route of electricity generation [75]. In view of the increasing rate of energy consumption globally, low-cost, sustainable, and reliable energy sources are ingredients for sustainable economic growth and development [76]. In this process, incident solar radiation is used for power generation using photovoltaic solar cells. Therefore, solar energy has the potential of meeting the economic energy need for electricity and other purposes. No chemical or mechanical work is required in the conversion of solar energy to electricity. As a result, solar energy-driven electricity has zero emissions, thereby making it the most environmentally friendly energy compared to other renewable resources [77]. However, despite high proficiency and the environmentally friendly benefits offered by solar photovoltaic (PV) systems towards addressing the lingering energy crisis, its high cost is considered a major limiting factor to its large-scale use. To address this, incentives in the form of financial support and tax-free import waivers need to be granted to companies as a way of inspiring/motivating more investment in solar PV systems [78]. Additionally, the ease of installation with cheap maintenance labor as compared to other power generation systems increase investment in solar PV systems [79]. Other benefits include zero risk, safe use, low maintenance costs, and high durability [80]. It is forecasted that the PV-powered electricity share will be more than 20% across the world by 2050 [81]. However, Sunanda et al. [82] reported that the amount of solid waste produced from the disposal of solar panels has not been accurately determined, and this will become a problem for the photovoltaic energy sector in the future. The waste from end-of-life solar panels is harmful to the environment and has the potential to produce 300-fold more toxic waste than nuclear plants.

Therefore, the integration of solar PV into DCS could minimize GHG emissions emanating from heating and cooling systems. Thus, a net-zero energy building is that in which the building system is completely serviced by renewable energy resources [83].

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Consequently, building systems for cooling purposes are highly enriched with solar PV-generated electricity to achieve the electricity load. In most designs, integrating solar PV into the DCS serves as a primary energy source while grid electricity is a secondary energy source [84]. With this, solar PV systems can significantly contribute to the cooling energy requirements in buildings via the support of artificial lighting systems and visual comfort, guaranteeing healthy natural lightening and producing solar electricity and solar heat at the same time [85,86]. In addition, the building cooling system will be supported by solar PV for both residential and district systems with a single central control unit. Therefore, due to the efficiency, cheapness, and abundance of solar energy for integration into DCS, increased adoption of the technology among residential, commercial, and government establishments is witnessed.

3.5. The Use of Surface Water in DCS

Surface water is considered a sustainable source of energy capable of fulfilling the bulk energy consumption demand of cooling and heating systems in buildings. This type of energy resource has the maximum capacity and is often regarded as the most frequently utilized in DCS [12]. Studies have shown that numerous DCS located in coastline cities across the world utilize deep seawater as a cold source of energy. With this, solar energy is absorbed by the surface and bottom (below 500–1000 m) of the ocean with a temperature of approximately 25–30 and 4 °C, respectively [83]. In deep seawater, the DCS scheme functioned with numerous benefits including huge energy savings of approximately 90% and is cost-effective, ecologically safe, and available for as long as needed [2]. However, in the world's tropical oceans, seawater temperatures decrease with depth, due to the presence of the deep-water ocean hot sink because of issues linked to climate change.

Typically, within the tropical zone, the temperature is approximately 8 and 4 °C, slightly colder, at approximately 700 m and 1000 m in depth, respectively. However, if cool water is available in ample amounts, DCS chillers are not required. With this free cooling technology, the energy requirements of the DCS will significantly reduce [12]. As shown in Figure 3 of deep sea cold water, heat exchangers are used for the passage of the deep cold seawater from the surface to the central DCS plant [87]. Therefore, its abundance and ease of accessibility make it readily available and suitable for integration into DCS. Moreover, this technology offers the potential of supporting the required thermal comfort during hot seasons to residential, commercial, industrial, and government institutions/establishments. The economic viability of this process coupled with its increased efficiency make this process an attractive alternative for DCS to foster the sustainability of cooling technology.

3.6. The Economic and Environmental Analysis of Renewable Energy-Driven Systems for Cooling

The economic and environmental impacts of renewable energy-driven district cooling systems are significant and complex [84]. On the economic side, these systems offer cost savings over traditional air conditioning systems through their centralized design, reduced energy consumption, and lower maintenance costs. However, the initial investment required to implement these systems can be significant, and the long-term financial benefits depend on factors such as energy prices, government incentives, and system performance [88]. On the environmental side, the integration of renewable energy sources can greatly reduce carbon emissions by district cooling systems, as well as lower the impact of climate change [89]. However, a summary of the economic and environmental gains of renewable energy-driven systems for cooling is presented in Table 2. Harnessing the power of renewable energy systems can significantly reduce their greenhouse gas emissions and contribute to a more sustainable energy system. Furthermore, renewable energy sources are considered reliable and less susceptible to fuel shortages, price fluctuations, and other supply chain disruptions, making district cooling systems more reliable and less vulnerable to unexpected interruptions. Additionally, the use of these systems helps reduce dependence on finite fossil fuel resources and promote a more sustainable energy future by improving the stability of the energy system and reducing the need for backup power

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

from fossil fuels [66]. Overall, the economic and environmental impacts of renewable energy-driven district cooling systems are highly positive, but they are also subject to many uncertainties and challenges. To fully understand the benefits and drawbacks of these systems, further research and development are needed to assess their performance in different conditions and environments and to identify best practices for their implementation. In conclusion, the use of renewable energy-driven systems for district cooling can result in both economic and environmental benefits, making them a promising solution for sustainable energy production.

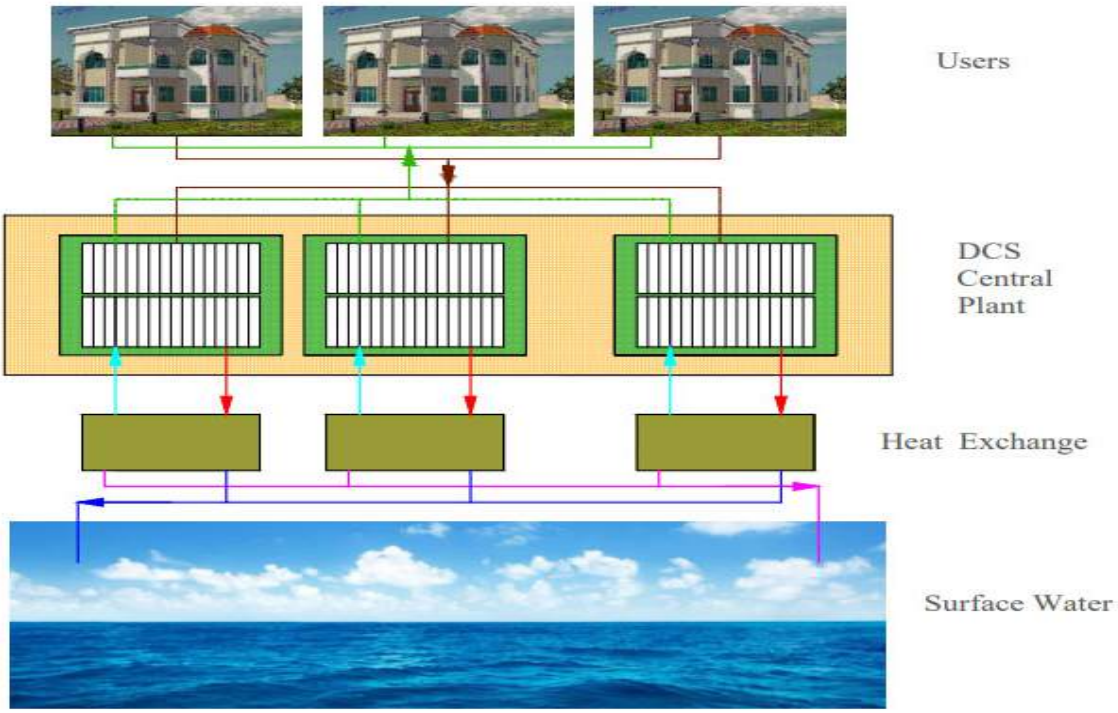

Figure 3. A modified version of the DCS using surface water; copyright by Elsevier 2019 [2].

Table 2. The economic and environmental advantages of incorporating DCS with various green energy systems.

Renewable Energy Type	Economic	Environmental	Ref.
Biomass energy integration into DCS	• Lower cost: Biomass-based materials are typically less expensive than traditional fossil fuels, reducing the operating costs of district cooling systems. • Renewable energy source: Biomass is a renewable energy source, reducing dependence on finite and expensive fossil fuels. • Its unlimited availability makes it cheap. • Job creation: The use of biomass in district cooling systems can stimulate the growth of local biomass production and processing industries, creating new jobs and economic benefits in rural areas. • Local availability: Biomass is often readily available in local areas, reducing transportation costs and energy losses associated with long-distance fuel transportation.	• It is safe and produces lower amounts of GHG. • Biomass is linked to a reduced risk of wildfire and an increase in sustainable ecology. • Reduced emissions: Biomass-based materials produce lower amounts of greenhouse gas emissions compared to traditional fossil fuels, improving air quality and reducing the carbon footprint of the district cooling system.	[90,91]

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Table 2. *Cont.*

Renewable Energy Type	Economic	Environmental	Ref.
Solar thermal energy integration into DCS	• Reduce power consumption, thereby lowering electric bills. • Lower energy costs: By using solar thermal energy, a district cooling system can reduce its dependence on traditional fossil fuels and lower its overall energy costs. • Improved energy security: Solar thermal energy can provide a local and renewable source of energy, reducing dependence on imported fuel and improving energy security. • Boost to the local economy: The integration of solar thermal energy into district cooling systems can create jobs and stimulate local economies, as well as increase demand for local goods and services.	• It is pollution free, with no GHG emissions after installation. • Decreased greenhouse gas emissions: Solar thermal energy is a clean and renewable energy source which reduces the emissions of greenhouse gases associated with fossil fuels.	[70,82,92]
Geothermal energy integration into DCS	• Reducing overdependence on imported energy, thereby decreasing the trade deficit. This in turn promotes the growth of an in-house healthy economy.	• The combustion of fossil fuels on site is dramatically lowered or eliminated. • Offers a significant reduction in GHG emissions and the environmental damage associated with non-renewable resource extraction.	[93]
Solar photovoltaic integration into DCS	• Offsets electricity-associated costs. • Requires little maintenance and is easily customized.	• Minimal air pollution, thereby enhancing the long-term health of humans. • Passive and active systems with the option to also provide cooling during warmer seasons using absorption chillers.	[94]
Surface water energy integration into DCS	• Waste accumulation benefits.	• Supports the circular economy through waste conversion to value-added products.	[70]

4. Vapor Compression Chiller Integration into Thermal Energy Storage

4.1. Thermal Energy Storage (TES)

The poor cooling performance of DCS led to the deployment of TES to assist in storing chilled water during times that require less cooling. This works by discharging cold energy to meet the cooling loads, particularly at peak demand. Integrating a TES tank into a DCS setup helps improve operational efficiency, enhance the life span of the DCS, and reduce high tariff charges for peak and off-peak periods of the day [95,96]. Therefore, the workload of the electricity grid in the DCS is supported through the deployment of TES, leading to lower energy consumption, and reducing the cost of refrigeration using high electricity consumption due to transitioning to off-peak hours. Moreover, TES technology uses water as its storage medium, which is readily available with high thermal capacity, thereby making this process economically viable and sustainable. Another promising feature is the lower technical complexity of the water storage medium in connecting networks of the DC system [97]. Further, ice storage is another storage medium that utilizes the latent heat of ice, thus resulting in a smaller storage volume [98]. Comparatively, the use of ice storage demands little storage space and a low evaporation temperature for production, leading to lower plant efficiency in cold energy production. On the other hand, higher temperatures affect the efficiencies of water-based storage tanks through increases evaporation, increased stratification, and acceleration of build up scale and deposit inside

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

tanks. Most importantly, the literature revealed that the environmental impact is reduced by approximately 40% following the integration of TES into the DCS [64]. Nevertheless, the efficiency of TES is also enhanced by the integration of a vapor compression chiller (VCC) but cost inevitably increases.

4.2. Vapor Compression Chillers (VCCs)

A vapor compression chiller (VCC) is a mechanical device/compressor that uses steam, electricity, or gas turbines in the refrigeration process and is often installed to supply chilled water to TES for charging purposes [99]. The process involves lowering the temperature in an enclosed space by extracting heat and dispatching it to a designated place [100]. The VCC system is composed of a compressor, an evaporator, a condenser, and an expansion valve as shown in Figure 4. Typically, the process involves the circulation of the refrigerant around the system, followed by high pressure condensing, with the evaporator vaporizing the refrigerant as the vapor pressure becomes lower [101]. However, the compression and expansion of the refrigerant are often facilitated by the compressor and expansion valves and, subsequently, the condenser serves to repel the heat from the refrigerant vapor. Studies have shown that data mining, simulations using different software, and data analytics are used to quantify energy saving and ultimately improve the energy efficiency of VCS in buildings. Further, other modeling tools reported in the literature include the grey box, which combines the qualities of both the physics-based and data-driven models [102]. Therefore, the energy efficiency of VCCs can be measured using different indicators such as the energy efficiency ratio (EER), the integrated part load value (IPLV), the seasonal energy efficiency ratio (SEER), and the seasonal coefficient of performance (SCOP) that involves seasonal chiller operations and capacity modulation. Therefore, the efficiency of the VCC and its overall performance is computed using the COP and the cooling load from measurements of electricity consumption is quite simple, thus the surrounding conditions and the chiller technology determine the COP value [103].

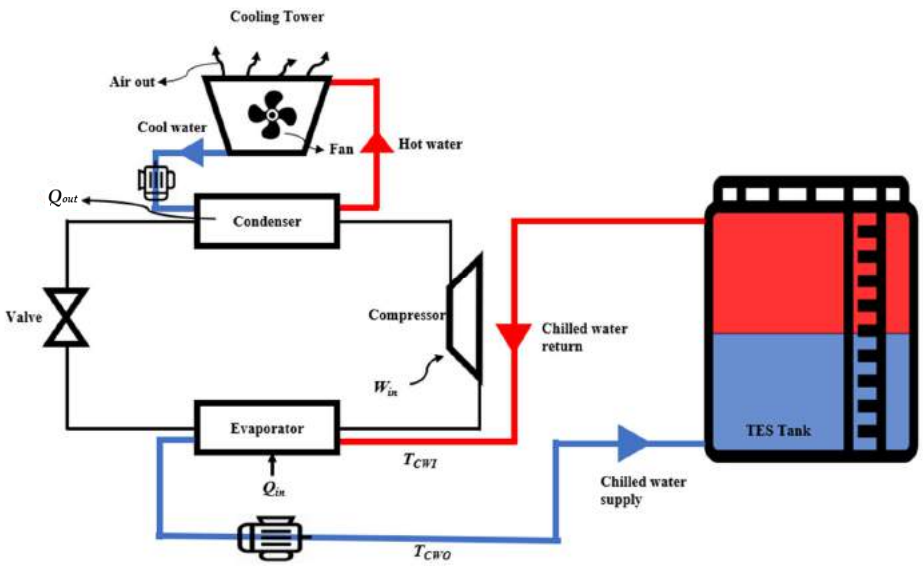

Figure 4. Schematic diagram of a vapor compression system adapted from [20].

Overall, the benefits of VCC/TEC integration into DCS are:

- Enhanced control and monitoring of industrial processes, leading to improved efficiency and reduced waste.
- Reduced dependence on fossil fuels and reduced greenhouse gas emissions.
- Optimization of energy consumption, reducing costs and further benefiting the environment [96].
- Economic and environmental benefits for selected countries as presented in Table 3.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Table 3. Environmental and economical advantages of implementing DCS, incorporating renewable energy sources, and integrating VCC/TEC into DCS outlined for certain countries.

Country	Energy Source/ Integration	Environmental Benefit	Economic Benefits	Reference
District cooling system				
Hong Kong	DCS powered by grid	Has no environmental gain	Lowere electricity consumption by the DCS especially for an ice storage system with 60% chiller priority. This in turn reduces the electricity tariff.	[102]
	✓	✓	Approximately 80% of the annual operating cost of DCS with ice storage compared to DCS optimized using a conventional method.	[103]
USA	✓	✓	In 2015, a sum of USD 421,434 was realized in one week (i.e., 1–7 July) as profit from the sales of electricity from the grid to cooling system stations and other heating sales.	[104]
Turkey	DCS powered by grid using coal-fired power plants	Lower emissions (not quantified)	No economic benefit was recorded.	[105]
Kuwait	DCS powered by grid using Natural gas	There is a 50% annual reduction in CO_2 emissions	The relative cost per ton-hour for cooling was reduced by approximately 53%.	[9]
District cooling system using renewable energy				
Saudi Arabia	DCS powered by solar system integration	• Minimal emission of GHG • Lower heat emissions	• Investment into the solar-driven system was improved, leading to more investment in the technology. • The lowest investment cost is recorded through the deployment of solar systems.	[106]
	✓	CO_2 emissions are reduced by an average of 500 tons (i.e., 70%) and 1400 tons per year relative to DCS with a centralized electrical compression chiller cooling plant	• The primary cost of the solar field, storage tank, and chillers is reduced through the system component size optimization. • The overall cost of DCS with PTC-driven double-effect absorption chillers is approximately 30% lower than that of DCS with ETC-driven single-effect absorption chillers.	[36]
Singapore	DCS powered by PV electric system integration	CO_2 emissions would be reduced by an average of 19.7% from 2020 to 2050	An estimate of three hudred and thirty million dollars, was earmarked for DC grid investment of the Singapore 2050 energy system, which is projected to save by up to 32.7% energy.	[107]
Sweden	DCS powered by biomass	Zero CO_2 emissions	Not reported.	[108]
Dubai	DCS powered by solar system integration	Not reported	Non-quantified economic savings associated with reduced electricity consumption, reduced peak demand charges and reduced CC investment costs.	[109]
District cooling system using vapor compressor cooling/thermal energy storage				
Malaysia	DCS integrated by TES/VCC	Lowest CO_2 emissions, reduced by approximately 40% as recorded by TES	Approximately 40% savings.	[20]

5. Conclusions and Future Research Priorities

This study reports the economic and environmental impact of DCS and the integration of renewables and TES with VCCs into DCS. This study identified a cost-effective, energy-efficient, and environmentally friendly cooling technology. The report also compares the

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

benefits of different cooling technologies, such as better comfort and reliability, as well as reduced maintenance and operating costs. However, traditional DCS technology has drawbacks, including high energy demand and excessive CO_2 emissions from fossil fuel combustion. To address these issues, the integration of renewable energy into DCS is proposed to minimize costs and reduce carbon accumulation. The implementation of solar energy in DCS in Saudi Arabia and Dubai reportedly led to a 35–70% reduction in their carbon footprint. Meanwhile, the integration of bioenergy into DCS is widely adopted in Finland and Sweden, in line with their green energy policies. In conclusion, the integration of renewables into DCS offers a feasible solution because it is efficient, cost effective, and environmentally friendly. Additionally, the integration of information processing and predictive control technologies will improve access to previously impractical renewable energy sources such as biomass, which has lower economies of scale and reliability challenges in the supply chain. Distributed energy generation units have greater potential for biomass by utilizing local supply resources. Lastly, the integration of TES with VCCs into DCS was reported to have been adopted and used successfully in Malaysia. This technology was also found to have offered an economic advantage of an approximately 40% cost reduction compared to DCS alone, which in turn reduces energy consumption and environmental impact. Overall, it can be established that the use of renewable energy technologies has the most significant influence on the system's environmental performance. Overall, this study highlights the potential for renewable energy-driven district cooling systems with thermal energy storage to contribute to a more sustainable and efficient built environment. Moreover, the challenges and uncertainties associated with these systems, and the need for further research and development to fully realize their potential, have been presented. Although renewables are considered expensive in some respects, policies such as tax import waivers and other incentives by the government would go a long way in upscaling the broader utilization of renewables. In conclusion, the following recommendations were made for the use of DCS technology.

- Increase government incentives: Encouraging the development and implementation of renewable energy-powered district cooling systems with thermal energy storage through government incentives such as tax credits, subsidies, and grants can help to overcome the initial investment hurdle and increase the adoption of these systems.
- Improve energy storage technology: Advances in energy storage technology, such as increased capacity, reduced cost, and improved performance, will play a key role in the future development and implementation of renewable energy-powered district cooling systems.
- Encourage public–private partnerships: Encouraging public–private partnerships between government agencies, utility companies, and private sector organizations can help to pool resources and expertise and increase the speed and scale of deployment of these systems.
- Develop new financing models: Developing new financing models, such as energy performance contracting and energy service companies, can provide innovative ways to fund the development and implementation of renewable energy-powered district cooling systems with thermal energy storage.
- Enhance public awareness and education: Raising public awareness and education about the benefits and potential of renewable energy-powered district cooling systems with thermal energy storage can help to build public support and drive demand for these systems.
- Implement smart grid technologies: Integrating smart grid technologies, such as demand response and energy management systems, into renewable energy-powered district cooling systems with thermal energy storage can help to optimize energy consumption, reduce energy waste, and improve system efficiency.
- The focus should be tailored towards exploring synergy among the co-technologies of DCS, renewables, and TES with VCC-integrated systems to effectively overcome many problems associated with the technology.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

- Deployment of modern learning tools such as machine learning to forecast the rate of energy efficiency and consumption in the building: This creates an avenue for comparison between the predicted results and the conventional results to detect possible defections.
- A holistic approach to sustainability evaluation should be incorporated in the environmental and economic assessment of the various technologies.
- Strategies for incremental development in terms of the challenges of system efficiency, cost, and sustainability would help these technologies become more viable in the nearest future.

Abstract: The problem of global warming and climate change has attracted global attention, and reducing the concentration of CO_2 in the atmosphere is an important step towards solving the problem. This paper mainly introduces the current development status, research hotspots, challenges and some emerging technologies of carbon capture, utilization and storage (CCUS). Among CO_2 capture technologies, solvent absorption technology is currently the most mature and widely used technology, among which ionic liquid technology has great application prospects because its molecular structure can be designed and different functional groups can be connected. The surface functionalization of metal–organic frameworks in the adsorption method endows them with excellent CO_2 adsorption capacity. In CO_2 transportation, temperature and pressure must be considered in pipeline transportation, because they will affect the phase state of CO_2 transportation. The impact of impurities on CO_2 pipeline transportation is a challenge that affects pipeline design and transportation safety. In CO_2 utilization, the key to enhanced oil recovery, gas recovery and displacement of coalbed methane is to increase the recovery rate and increase the storage capacity at the same time. Only by strengthening the research on the adsorption behavior between CO_2 and CH_4 and revealing the relevant mechanism can innovative technologies be developed. The chemical utilization of CO_2 has formed many routes, but they all lack certain advantages. Most scholars are working on catalysts for CO_2 conversion, especially copper-based catalysts that can convert CO_2 into methanol. The conversion rate of CO_2 can be effectively increased through doping or process improvement. The coupling of electrocatalytic technology and renewable energy is an important development direction in the future. In CO_2 storage, geological storage is currently the most important method, especially in saline aquifers. There are currently critical issues concerning reservoir integrity and leakage potential that should be further investigated. CO_2 leakage will cause serious environmental problems, and the common monitoring methods are reviewed and discussed in this paper. Finally, the research status, hotspots and cooperation networks of CCUS are summarized by using CiteSpace software in order to help the development of CCUS technology. In addition, through the review and analysis, it is found that CCUS is faced with challenges such as low capture efficiency, difficulties in transformation and utilization, high operating costs, lack of strong support policies, and lack of international cooperation, which restrict the further development of CCUS.

Keywords: CCUS; capture; utilization; transport; storage

1. Introduction

In the past few decades, due to human activities such as fossil fuel power generation, more and more CO_2 in the atmosphere has been caused, and the greenhouse effect has become more and more obvious. This poses a huge threat to human and global security. At present, the CO_2 concentration in the atmosphere has exceeded 400 ppm, which is about 40% higher than before industrialization, and the surface temperature has increased by about 0.8 °C [1]. However, it is almost impossible to replace conventional power plants with clean energy power generation in the short term. Moreover, the International Energy

PERPUSTAKAAN NASIONAL

Agency reported that although affected by the COVID-19, global carbon emissions have plummeted. However, it is expected that with the gradual improvement of the epidemic situation in various countries, carbon emissions will rise further, and there is no sign that peak carbon emissions have yet been reached. In this case, to achieve the goal of controlling the temperature rise to 2 °C, we must accelerate the transformation of the energy system. In addition to vigorously developing new energy sources, carbon capture, utilization and storage (CCUS) technology has also attracted the attention of the academic community. This is an emerging technology with the potential to reduce CO_2 emissions on a large scale. It is considered to be the key technology for mitigating climate change and has attracted great attention from governments, industry and academia in recent years. As shown in Figure 1, CCUS technology refers to the selective removal of CO_2 from the air flow of emission sources (power plants, steel plants and cement plants) by using capture systems, and then the CO_2 is transported to the storage site through pipelines for storage or utilization in the plant. CCUS can help better manage CO_2 concentrations.

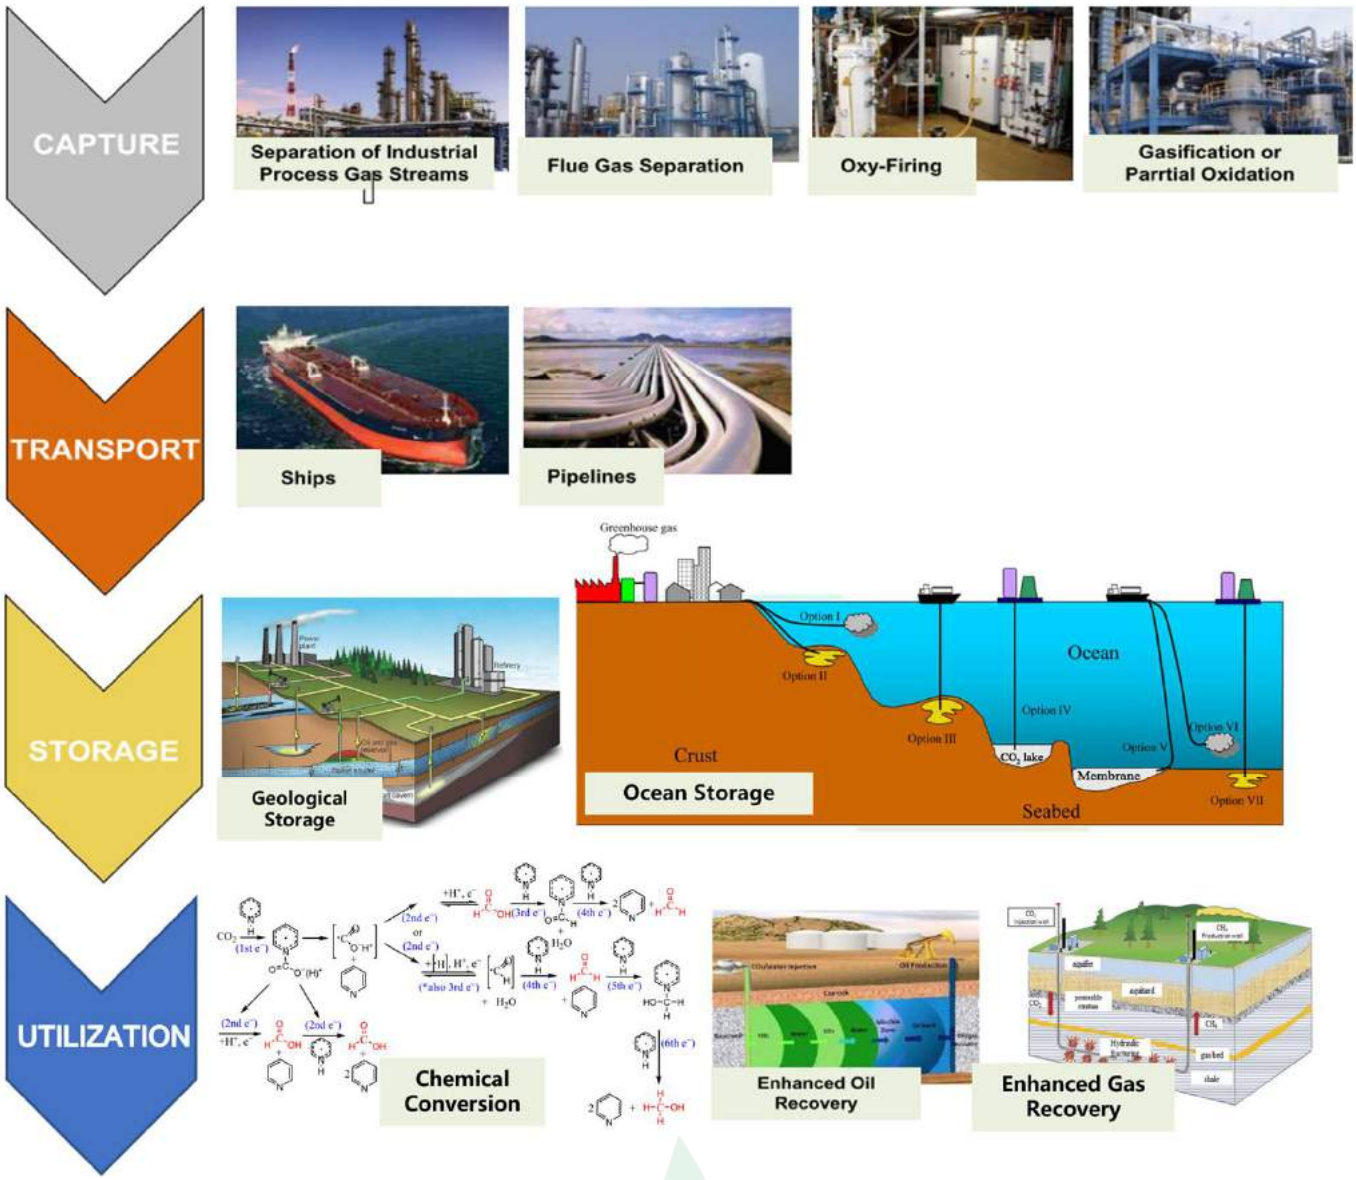

Figure 1. CCUS technology [1–5].

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

The development level of CO_2 capture technology is the key to the whole CCUS technology. It mainly uses methods such as solvent absorption, solid adsorption, membrane separation and low-temperature separation to separate CO_2 in the mixed gas from other components. CO_2 transport plays a connecting role in CCUS technology, which connects carbon capture with storage and utilization. It can ensure the safe and economical operation of the CCUS system. Pipeline transportation is the most common mode of transportation. The cost of transporting one ton of CO_2 is 1–10 USD/km. The demand for CO_2 pipeline construction will increase significantly in the future. The utilization of CO_2 has attracted extensive attention. It is currently mainly used for enhanced oil and gas recovery, but people are paying more attention to other utilization methods of CO_2, including chemical industry raw materials, mineralization, biological utilization and the food industry. People have developed a variety of conversion routes and methods to convert CO_2 into chemicals, but most of them are in the pilot stage, mainly because of the high conversion cost and low conversion efficiency. The amount of CO_2 used every year is very small, which is far lower than the emission of CO_2. Moreover, the used CO_2 will be re-released at the end of the product life cycle. But its importance lies in the indirect reduction of CO_2 emissions by avoiding the use of fossil carbon. In the future, if we want to achieve the goal of carbon neutrality, CO_2 storage will still be the main strategy. CO_2 storage can be divided into geological storage and ocean storage. Geological storage is the most common form of storage, especially in saline aquifers. It sequesters CO_2 from the atmosphere, and over time the CO_2 is converted into carbonate minerals for permanent storage.

CCUS technology has achieved remarkable development in recent years. It can ensure large-scale low-carbon utilization of fossil energy. It is a necessary solution for the decarbonization of industries that are having difficulty reducing emissions. There are more than 30 CCUS programs in operation around the world. Among them, North America is dominated by CO_2 flooding. In Europe, ocean storage of CO_2 is the main focus. Most of these commercially operated projects use chemical absorption technology or physical absorption technology to capture CO_2 and use pipeline transportation or ship transportation technology to transport it. At present, relevant research on CCUS is constantly increasing, but most of them are focused on one side, as shown in Table 1, and few articles can systematically and comprehensively review various techniques in CCUS. A detailed review of various technologies in CCUS will help people better understand CCUS technology and help in its development. In addition, CCUS also faces many challenges in each link, which restricts the implementation of CCUS projects. By analyzing the existing problems and challenges of CCUS technology, this paper points out the future development direction of CCUS technology.

In this review, we followed the following steps: First, we used keywords such as CCUS, CO_2 capture, CO_2 transportation, CO_2 utilization and CO_2 storage to search the Web of Science core database. The search content does not include books and core papers, and the period covered is 2006–2021. Then, by simply reading the abstract, we screened the relevant literature. In this step, we screened 558 pieces of literature. Finally, we further screened the downloaded literature by careful reading and reduced the number to 265 articles. The screening criteria were to see whether they are closely related to the theme of this review. Finally, this paper will examine CCUS technology in detail through four parts: CO_2 capture, CO_2 transport, CO_2 utilization and CO_2 storage based on the 265 articles. This paper mainly introduces the current development status, research hotspots, challenges and some emerging technologies of CCUS technology. At the same time, CiteSpace software is used to measure and analyze these documents and analyze the research status, trends and cooperation.

2. CO_2 Capture

According to the combustion process of fossil fuels and the technical basis of the CO_2 capture system, carbon capture can be simply divided into three processes: post-combustion capture, pre-combustion capture and oxyfuel combustion capture. Post-combustion capture mainly refers to the capture of CO_2 from the waste gas produced by the combustion of fossil fuels or other carbon-containing fuels. It is currently the most widely used carbon capture strategy. Its technology is currently highly mature and has a large number of commercial applications [12]. Compared with pre-combustion capture and oxyfuel combustion capture, it has several advantages, for example, the transformation of CO_2 emission sources is small, it can be quickly applied to existing power plants, and the later maintenance cost is small. It also has a small impact on production activities and high flexibility [13]. Of course, the carbon capture efficiency is low due to the low content of CO_2 in the gas after combustion [14]. At the same time, the separation effect will also be affected because the gas after combustion contains other impurities. In conclusion, post- combustion capture technology needs to develop efficient and ideal adsorption materials, and improve the energy efficiency of post-combustion carbon capture equipment. At present, most research focuses on post-combustion capture strategy [15]. Common capture technologies are shown in Figure 2, which will be described in detail below.

2.1. Solvent Absorption Technology

Solvent absorption technology is the most widely used CO_2 capture technology at present, which is mainly used for post-combustion capture and pre-combustion capture. Due to its good separation effect, low application cost and relatively mature technology, it is the key technology to implement the "Zero Emissions Energy Strategy". In this article, we will divide solvent absorption into the physical absorption method, chemical absorption method and the physical–chemical absorption method according to whether physical and chemical reactions occur in the process of solvent absorption. In addition, since the current research focus has been extended to the use of solvent mixtures, we will also discuss them in this article.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

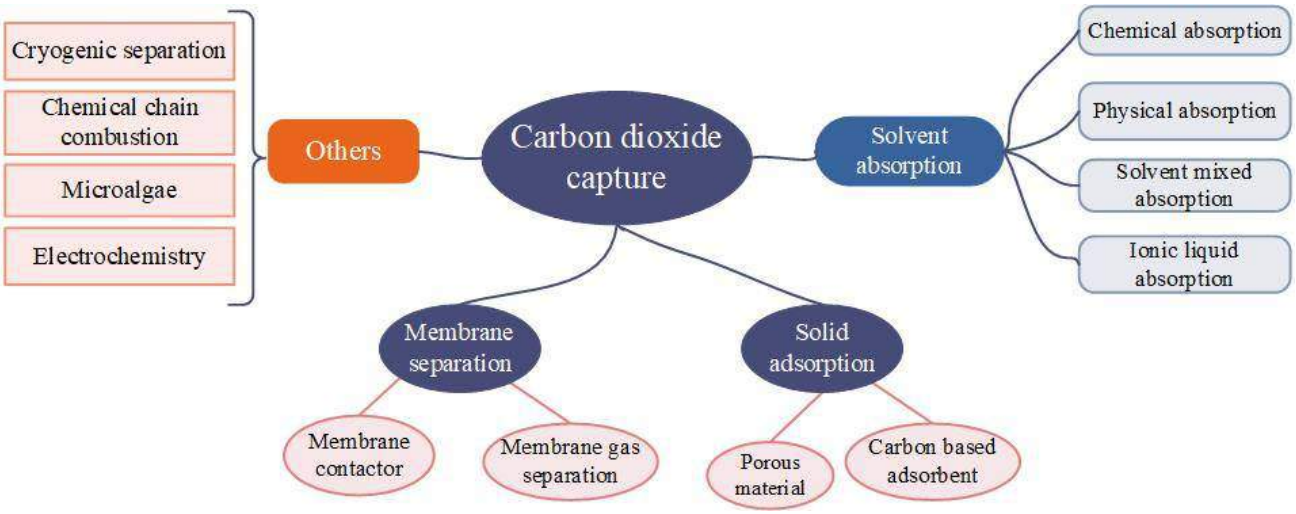

Figure 2. CO_2 capture technology.

2.1.1. Chemical Absorption Technology

Chemical absorption technology mainly uses a liquid solution to absorb CO_2 through a chemical reaction, and the absorbed CO_2 is released for storage or utilization through reverse decomposition. Typical CO_2 chemical absorption technology is shown in Figure 3, which mainly relies on the absorption tower to remove CO_2 in the flue gas, and relies on the stripping tower to desorb and regenerate [16].

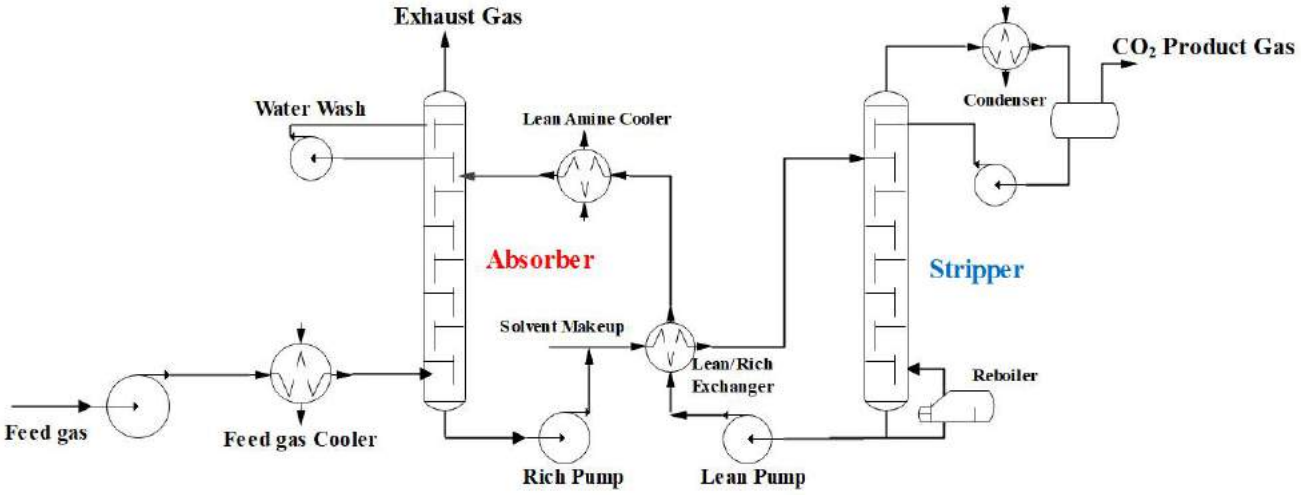

Figure 3. Typical chemical absorption separation CO_2 process [16].

In chemical absorption technology, commonly used solvents mainly include ammonia, potassium carbonate, amino solvent and alkaline solvent [17]. Among them, amino solvents are considered to be the most developed among the currently studied solvents and are widely used in post-combustion carbon capture (PCC). Its disadvantage is that the amine is easily degraded during long-term operation, and its capture property is reduced [18]. It has the advantages of high chemical reactivity with CO_2, low production cost and large-scale stable operation [19]. Ammonia aqueous solution is superior to conventional ammonia solution in CO_2 capture, so it is a good substitute. However, due to its high volatility, it will escape into the airflow, so there are still technical obstacles [16].

Chemical absorption technology has some applications, but there are still some problems to be solved. For example, compared with solid adsorption technology, its energy consumption is high, compared with physical absorption technology, its efficiency is low, the absorbent suffers evaporation loss and oxidative degradation, and the absorbent will

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

cause corrosion to equipment, etc. In practical application, the negative effects of SO_x, NO_x and oxygen on absorbents should also be considered in developing more appropriate models [20]. In order to overcome these shortcomings, many scholars began to study some additives and mixtures (such as piperazine (PZ) and PZ derivatives). Reducing the energy consumption of chemical absorption technology is an important research direction for the future. Energy consumption can be effectively reduced by process improvement (heat integration strategy) or by using solvents with high heat absorption.

2.1.2. Physical Absorption Technology

Physical absorption technology can be applied when CO_2 and liquid solvents do not undergo obvious chemical reactions, and its operation is based on Henry's Law [20]. Physical absorption is suitable for use under high pressure and low temperature so that the solubility of the gas in a liquid solvent will be greater [16]. The physical absorption method has a simple process, high operating pressure, and can capture some other harmful gases, but the recovery rate of CO_2 is low, which is usually applied to situations where the requirements for gas purification are not high.

Physical absorption methods usually include the propylene carbonate method, the polyglycol dimethyl ether method and the low-temperature methanol washing method. Different physical absorption methods have different advantages and disadvantages, see Table 2 for their comparison. Physical solvent has good application in integrated gasification combined cycle (IGCC) power generation facilities, with high capture efficiency and low energy loss [16,21].

Table 2. Comparison of physical absorption methods.

Method	Propylene Carbonate Method	Polyethylene Glycol Dimethyl Ether Method	Low-Temperature Methanol Washing Method
Applicable conditions	3~7 Mpa >25 °C	1.5~14 Mpa 1~25 °C	3~8.1 Mpa −10~−70 °C
Characteristic	the solvent is cheap and non-toxic, suitable for absorbing CO_2 from natural gas and crude hydrogen	the process flow is simple, the operation flexibility is large, the one-time purification degree is high, and the total energy consumption is low	methanol is cheap and easy to obtain, with good selectivity, thermal stability and chemical selectivity, and low operating cost

Chemical absorption technology and physical absorption technology have different advantages and disadvantages. Chemical absorption technology is suitable for absorbing CO_2 at low pressure, and physical absorption technology applies to absorbing CO_2 at high pressure. In chemical absorption technology, due to the chemical reaction between CO_2 and solvent molecules in forming chemical bonds, it is highly selective to CO_2. In physical absorption, although there is a weak interaction between CO_2 and solvent, its regeneration energy is low [22]. Therefore, is there a method that can combine the advantages of these two methods? For this reason, people began to study solvent-mixing technology.

2.1.3. Solvent Mixed Absorption Technology

Single solvent systems have been deeply studied, and many properties of solvents have been defined. At present, the research focus has been on the research and development of solvent mixtures, which can be developed by mixing various solvents and synergistic effects with accelerants. At present, promising solvent mixtures include amine-based blends, NH_3-based blends, K_2CO_3-based blends and deep eutectic solvents. These blends mainly combine the advantages of different solvents. For example, ethanolamine sulfolane water is an amino blend, which combines physical and chemical solvents, and has the advantages of both methods. Alcohol amine is a chemical solvent, which can absorb organic sulfur in the mixed gas and can also dissolve part of H_2S and CO_2. Sulfolane is a physical solvent, which can absorb CO_2 in the mixture. This solvent has a wide application range,

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

low CO_2 content in purified gas and low corrosivity [22]. The mixture of MEA + MDEA is a typical synergistic effect. The reaction rate is increased by adding MEA, and the regeneration energy is reduced by adding MDEA.

Deep eutectic solvent is a new green solvent developed to overcome the high price and toxicity of traditional ionic solvents. Usually, two components are mixed according to a certain molar ratio, and the melting point of the eutectic solvent formed is usually lower than that of each component. Deep eutectic solvents have many advantages, such as low price, easy degradation, and little environmental pollution, and are suitable for large-scale preparation [18,23]. The most common deep eutectic solvent is a combination of quaternary ammonium halide and hydrogen bond donor [24,25]. At present, the research and development of deep eutectic solvents are still in the initial state. Although much progress has been made, there is still some distance to go before large-scale commercial use.

2.1.4. Ionic Liquid Absorption Technology

An ionic liquid is a kind of "green solvent", which has the advantages of wide operating pressure, low corrosion, and easy separation of products. The designability of its molecular structure creates opportunities for the design of ionic liquids. By connecting different functional groups, ionic liquids for different purposes can be obtained [26]. The common functional groups include amine, fluorine atom, hydroxyl, etc. The introduction of cation in an amino group is more effective, and ionic liquids with multiple amine sites usually have higher CO_2 absorption capacity than ionic liquids with one primary amine group. Ionic liquids containing hydroxyl groups have good separation performance of CO_2 at low pressure [27]. Xu [28] proved that the addition of super bases during the preparation of ionic liquids can effectively improve their ability to capture CO_2.

Of course, in addition to the influence of functional groups, the length of the alkyl chain and the type of anion will affect the CO_2 absorption capacity and viscosity of the ionic liquid [26,29]. Ionic liquids usually have high viscosity, especially those containing amino groups. This is usually due to the formation of hydrogen bonds in ionic liquids. The viscosity of ionic liquids can be reduced by introducing hydrogen receptors, or by mixing with organic solvents [27,30]. H_2S and CH_4 need to be separated before CO_2 capture because they will reduce the solubility of CO_2 and the selectivity of ionic liquids [31].

Although ionic liquids have great application prospects in CO_2 capture, most of the current applications of ionic liquids are limited to laboratories. Ionic liquids are expensive and the production process is complex, which are the main factor hindering the large-scale application of ionic liquids [32]. In addition, the potential toxicity and non-degradability of ionic liquids also hinder the large-scale application of ionic liquids. Thermodynamic models of CO_2 and ionic liquid systems also present challenges that require further study in the future.

2.2. Solid Adsorption Technology

The solid adsorption technology is mainly realized by the intermolecular attraction between the gas or liquid and the active point on the solid adsorbent. The adsorption of CO_2 by an adsorbent is usually realized by physical adsorption or chemical adsorption [33]. Good adsorbent, regeneration process and adsorption cycle time are required in the adsorption process [34]. This paper will mainly discuss the research progress of solid adsorbents by reviewing: carbon-based adsorbents, porous materials and other adsorbents.

2.2.1. Carbon-Based Adsorbent

Carbon-based sorbents mainly refer to materials composed of carbon atoms, which are simple to prepare and low in cost. They are usually used to capture CO_2 under high pressure because the adsorption capacity of CO_2 usually increases with the increase of pressure. The amount, size and distribution of voids in carbon-based adsorbents play an important role in CO_2 capture. By adding various functional groups on the surface of the carbon-based adsorbent, its carbon capture performance can be optimized [35]. In

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

the carbon matrix, increasing the pH of some parts of the surface will change the charge distribution on the surface and enhance its adsorption capacity [36]. The interaction between carbon-based adsorbents and CO_2 is very weak, so this presents a challenge for the selectivity and capacity of carbon-based adsorbents, especially at high temperatures and low partial pressures. Common carbon-based adsorbents include biochar, activated carbon and graphene-based adsorbents.

Biochar has a high specific surface area, micropore, porosity and various functional groups. Its structure and surface properties determine that it is an excellent CO_2 adsorbent. Biochar is an environmentally friendly and economical material [34,37–40]. Activated carbon is a kind of widely used carbon-based adsorbent. Its adsorption capacity is lower than that of zeolite or molecular sieve, and it will decrease significantly with the increase in temperature [33,41]. Activated carbon raw materials have a wide range of sources, with a wide range of pore size distribution and pore structure, and its manufacturing cost also has huge advantages [42]. Activated carbon produced by biomass containing heteroatoms (Such as O, S, P and N) can better absorb CO_2 [43]. Activated carbon can be divided into physical activated carbon and chemical activated carbon according to the activation mode. Different reaction conditions and activated chemicals will affect the physical and chemical properties of activated carbon, such as specific surface area, surface functional groups, shape, etc. [44–49]. Future research work on activated carbon will focus on improving its adsorption capacity and selectivity at low CO_2 partial pressure and producing adsorbents with adjustable active surface area and pore size. Graphene-based adsorbent is a carbon nano material, because its two-dimensional and hexagonal-filled lattice structure is similar to a honeycomb single carbon layer, and the active functional groups on the surface make it have good physical and chemical properties [50–53]. Graphene has a poor CO_2 adsorption effect, and its adsorption performance can be enhanced through activation, because activation can make graphene produce a three-dimensional structure, giving it a large surface area [54]. At present, the most effective graphene-based adsorbent is PANI/HEG (polyaniline/hydrogen exfoliated graphene), which has good cycle performance [55]. Future research on graphene is mainly aimed at improving its CO_2 adsorption capacity by attaching different functional groups and heteroatoms to its surface.

2.2.2. Porous Material

At present, many porous materials are widely studied for carbon capture. Porous materials have the advantages of high absorption efficiency and large adsorption capacity. The pore diameter, geometric shape and specific surface area of porous materials will affect the CO_2 capture effect. The commonly used porous materials include zeolites, metal–organic frameworks (MOFs) and mesoporous materials.

MOFs are emerging crystalline porous materials, which have the advantages of high pore volume, structural diversity, easily adjustable pore structure and surface functionalization [56,57]. MOFs are widely used in gas storage, drug delivery and heterogeneous catalysis, but their application in the selective adsorption of gas is one of the most active research fields at present [41]. MOFs can be functionalized by different methods to improve their CO_2 adsorption capacity. Common methods include adding polar functional groups, opening metal sites and modifying with Lewis basic sites [41,56,58]. These methods can better exploit the tailorability of MOFs, making them possess excellent CO_2 adsorption capacity. However, the cost of production and utilization of MOFs is too high at present, so it is difficult to use them on a large scale. In addition, the synthesis process of MOFs will cause environmental pollution, which also limits its application. In the future, reducing its synthesis cost and environmental pollution during the synthesis process are the main research directions.

Zeolite is a porous crystalline material composed of aluminosilicates, and most zeolites for CO_2 capture are synthetic. Synthetic zeolite can control its porosity and crystallinity in the process of synthesis, so it has more advantages than natural zeolite in capturing CO_2. The zeolite frame is of a microporous structure, and its pore size can be adjusted, so the

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

zeolite for CO_2 adsorption can be customized [59]. When most zeolites encounter water molecules, their CO_2 capture performance will decline. However, the hydrophobicity of zeolites with a higher silicon–aluminum ratio will be enhanced, and the hydrophobicity can also be increased by introducing hydrophobic functional groups [60]. Although synthetic zeolite has good trapping performance, its application is restricted by its high synthetic cost and environmental pollution.

During the past decade, mesoporous materials have become favorable candidates for CO_2 capture materials. Common mesoporous materials include mesoporous silica and mesoporous metal oxides. Silica is one of the most abundant substances in the world. Mesoporous silica is usually prepared by the Stöber method, and its pore diameter and specific surface area can be easily adjusted [59]. Mesoporous silica is a CO_2 adsorbent suitable for amine loading. The rich hydroxyl groups on the surface of silica are conducive to amine functionalization and improve its CO_2 adsorption capacity [61]. Common mesoporous metal oxides include TiO_2, MgO, alumina and cerium oxide [62–64] in which mesoporous ceria has the largest CO_2 adsorption capacity. TiO_2 can also quickly absorb CO_2.

2.3. Membrane Separation Technology

Membrane separation technology can generally be divided into gas separation membrane and gas absorption membrane. The working principles of the two membranes are shown in Figure 4. The gas separation membrane (Figure 4a) is mainly used to separate gas by permeating one or more gases from one side of the membrane to the other side through the selectivity of the membrane. The driving force is the pressure difference of the gas to be separated on both sides of the membrane. The gas absorption membrane (Figure 4b) is mainly used to selectively absorb gas through a chemical absorption solution, and the membrane only serves to isolate gas and absorption solution.

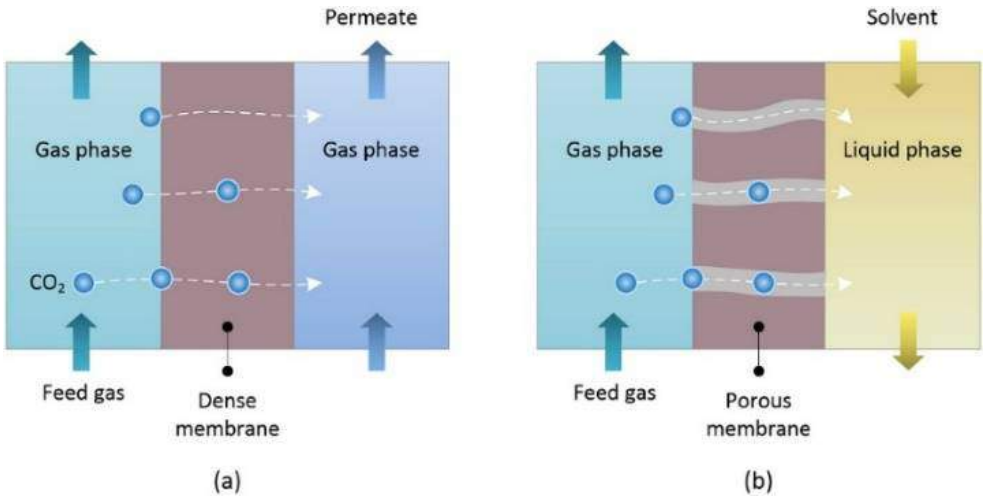

Figure 4. Schematic of (**a**) membrane gas separation (MGS) and (**b**) membrane contactor (MC) for CO_2 removal. Reproduced with permission from [65], Elsevier, 2019.

Gas separation membranes can be divided into three categories: inorganic membranes, organic polymer membranes and mixed matrix membranes. The relationship between the selectivity and permeability of most polymer membranes is shown in Figure 5. The permeability of polymer membranes with high selectivity is generally poor. In order to solve this problem, people began to study mixed matrix membranes. Norahim et al. [66] discussed the influence of different fillers on composite membranes. For example, mixing carbon nanofibers with polysulfone can improve its selectivity and permeability. The dendriform mixed matrix membrane is composed of polyether block amide (PEBA), polyethylene glycol (PEG) and nano-X zeolite, its CO_2 permeability and selectivity increase with the increase of feed pressure and PEG loading [67]. Some studies have shown that the addition of MOF can improve the performance of mixed matrix membranes in CO_2/CH_4 separation,

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

but there are still challenges in its preparation, such as poor compatibility and defects in the membrane matrix [68]. In the future, the commercialization of membrane separation technology can be accelerated by strengthening the research on mixed matrix membranes.

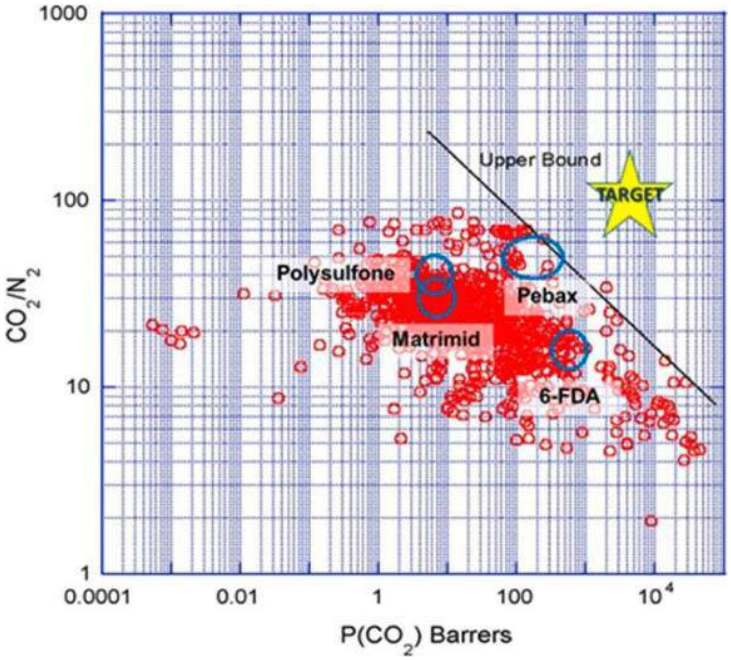

Figure 5. Correlation between polymer selectivity and permeability. Reproduced with permission from [66], John Wiley and Sons, 2018.

The gas absorption membrane mainly relies on the selectivity of the absorption liquid to achieve the purpose of separating and absorbing CO_2. Under ideal conditions, the gas absorption membrane operates in a non-wetting mode, so there should be only a gas phase in the membrane pore. In order to ensure that the liquid phase will not penetrate the membrane pores, microporous membranes made of highly hydrophobic polymers are usually used [65,69–71]. Improving the hydrophobicity of the membrane is the key to solving the problem of membrane wetting. The direct use of highly hydrophobic materials will increase the cost. Usually, a thin layer of such materials is coated on the cheaper membrane to reduce the cost. Another method is to improve the hydrophobicity of the membrane by changing the surface roughness and surface tension energy [72]. In addition to studying membrane materials, an in-depth understanding of wetting mechanisms related to membrane performance and operating conditions should also be gained.

Membrane separation technology can also be divided into promoted membranes and non-promoted membranes. The action mechanism of a non-promoted membrane mainly depends on the "solution diffusion" transport process. In addition to the "solution diffusion characteristics", the transport promotion membrane also includes an active transport mechanism to improve the permeability and selectivity of membrane materials. Supported liquid membranes (SLMs) are the first kind of transport-promoting membranes developed. They are non-dispersive liquid membranes, which mainly fill the pores of porous materials with liquid through capillary force as a selective material. It is generally divided into two types: mobile carrier and fixed carrier [73]. When ionic liquids are used to fill the pores, ionic liquids are mobile carriers, usually called SILMs. The interaction between ionic liquids and carriers will affect the distribution and separation performance of ionic liquids on carrier pores. For example, SILMs with hydrophobic carriers are more stable than SILMs with hydrophilic carriers [74,75]. Ahmad et al [70]. found that the higher the content of the ionic liquid in the membrane, the lower its selectivity. When using nano porous or porous oxide as the base membrane, the selectivity and permeability of ionic liquids can be enhanced [76]. The fixed-position carrier membrane uses the inherent

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

chemical reaction with the fixed position to "jump" CO_2 from one fixed carrier to the next through the membrane during CO_2 capture. The research and development of promoted membranes are helping to improve permeability and selectivity [77].

2.4. Other Technologies

2.4.1. Low-Temperature Separation Technology

Low-temperature separation technology is a green method, which uses the difference of relative volatility of each component in raw materials to separate each component by distillation [78]. Sreenivasulu et al. [79] compared several low-temperature separation methods and found that condensation rotary separation is the only feasible option, with less energy loss and higher CO_2 separation yield. Belaissaoui et al. [80] studied the mixed membrane low-temperature process for CO_2 capture after combustion. The results showed that when the imported CO_2 concentration was 30%, compared with the single low-temperature method, the mixed process could effectively improve energy efficiency. Xu et al. [81] studied a cryogenic capture system to capture CO_2 in the flue gas of an LNG power generation system. This system can make full use of the cold energy of LNG during gasification. The results show that if the flue gas temperature can be reduced to below −140 °C, the CO_2 recovery rate can reach 90%. Song et al. [82] summarized the existing low-temperature CO_2 capture technology and concluded that low-temperature separation technology is more competitive only when low-cost cold energy is available. Low-temperature separation technology is only suitable for high-concentration CO_2 flow (above 90%), not for dilute CO_2 flow. In the future, we should optimize the operation parameters and process of the low-temperature capture system and make full use of the cold energy of the remaining gas after capture [10].

2.4.2. Microalgae

Among photosynthetic organisms, microalgae capture CO_2 through its photosynthesis, which is a potential and promising candidate organism for carbon capture. The photosynthetic rate of microalgae is higher than that of terrestrial plants. Its cell structure is simple, its growth rate is fast, and its environmental adaptability is strong. Therefore, CO_2 biological fixation through microalgae is more effective than that of terrestrial plants. Meanwhile, algae have a carbon-enrichment mechanism that inhibits photorespiration [82,83]. Song et al. [84] summarized the existing absorption-microalgae composite CO_2 capture technology and concluded that the absorption microalgae composite CO_2 capture technology can overcome the shortcomings of traditional absorption and microalgae fixation, that is, the absorption technology has high energy consumption for regeneration and low CO_2 solubility in microalgae solution. It is very promising to use microalgae to directly capture CO_2 in the flue gas generated by fossil fuel power plants or steel plants. Thomas et al. [85] discussed four strategies for biological mitigation of CO_2 in flue gas, and they concluded that it is the most economical to supply flue gas directly to the microalgae photobioreactor, but it is necessary to select appropriate microalgae species to withstand the composition and high temperature of flue gas. It is also found that directly injecting flue gas into the pond containing microalgae can increase biomass productivity by 30%, which may be due to the presence of supplementary nutrients in the flue gas, resulting in the fertilizer effect [86]. Of course, CO_2 capture by microalgae also has disadvantages. It requires specific geological and geomorphic structures, expensive separation equipment, uncertainty and long-term leakage risk. Therefore, in order to apply the microalgae capture technology on a large scale, it will be necessary to develop carbon source treatment technologies with different chemical forms and distribution characteristics, improve the utilization rate of industrial waste gas and optimize the cultivation process [87].

2.4.3. Chemical Looping Combustion Technology

The basic principle of chemical looping combustion technology (CLC) is to decompose the traditional combustion of direct contact reaction between fuel and air into two gas-solid

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

reactions with the help of an oxygen carrier. The fuel and air do not need to contact, and the oxygen in the air is transferred to the fuel by the oxygen carrier. The oxygen carrier is periodically oxidized and reduced with air and fuel. CLC technology is considered the most cost-effective CO_2 capture technology with the least energy loss. Its flow chart is shown in Figure 6. Oxygen carriers are usually transition metal oxides, because they are easy to reduce and reoxidize, and are suitable for recycling between two reactors [88,89]. Sajen et al. [90] studied the mixture of transition metal oxides (Such as CuO) and manganese oxides in CLC and found that the mixed oxides showed good activity for the oxidation of syngas fuel. Adanez et al. [91] compared the carbon capture efficiency of in situ gasification chemical chain combustion process (iG–CLC) and oxygen uncoupling chemical chain process (CLOU) under different reactor temperatures and different coals. The results show that the carbon capture efficiency and combustion efficiency of CLOU are better than those of iG–CLC. Hu et al. [92] compared various commonly used oxygen carriers and concluded that calcium oxide is an ideal CO_2 carrier material with low cost, non-toxic and renewable. Among many chemical chain combustion reactors, a fluidized bed reactor is considered to be the best choice for large-scale application of chemical chain combustion technology. The fluidized bed reactor provides high solid circulation, which makes the fuel fully contact with the oxygen carrier in the fuel reactor, providing sufficient oxidation and reduction time for the oxygen carrier [93].

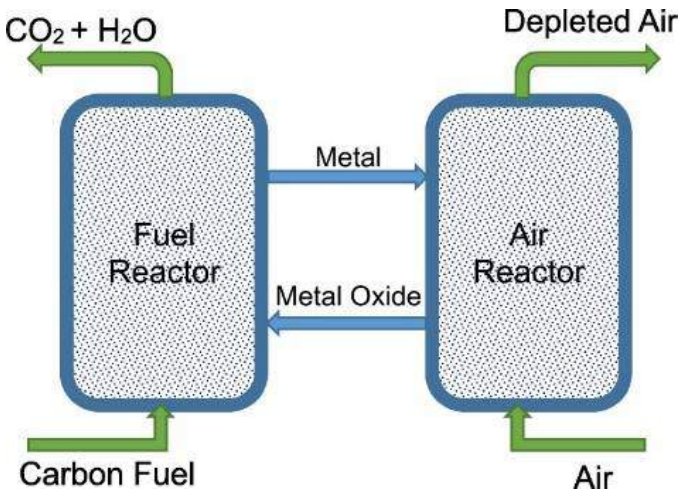

Figure 6. Schematic diagram of chemical looping combustion. Reproduced with permission from [93], Elsevier, 2021.

2.4.4. Electrochemical Technology

Electrochemical technology mainly uses an electrochemical reaction to selectively separate CO_2 from the mixture, absorb and release CO_2 through electrolyte solution, and regenerate electrolytes with an ionic conductive membrane. This method can capture CO_2 at atmospheric concentration levels, low pressure and low temperature, with low energy demand. Most electrochemical methods capture and recover CO_2 by moving the pH value of the working solution between acidic and alkaline pH values [94]. Muroyama et al. [95] reviewed the research progress of electrochemical separation of CO_2 and found that electrodialysis using liquid electrolytes to capture solution is the most intensively studied electrochemical method at present.

Fuel cells and their hybrid system are one of the effective technologies to reduce CO_2 emissions, which have the advantages of being clean and efficient. A high-temperature fuel cell is an electrochemical device, which is usually composed of an electrolyte, anode and cathode. Common high-temperature fuel cells mainly include solid oxide fuel cells, molten carbonate fuel cells and direct carbon fuel cells. Wang et al. [96] compared and introduced these three fuel cells and their application prospects in carbon capture in detail. Although there are still many challenges in the application of high-temperature fuel cells

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

(such as the need to scale up fuel cell modules, and the high cost and safety of fuel cells), high-temperature fuel cells are still an excellent strategy for CO_2 emission reduction in power plants.

Zhang et al. [97] gave an overview of a new high-temperature electrochemical CO_2 transfer membrane. They compared several membranes made of different materials and evaluated some CO_2 capture reactors based on these membranes. At the same time, the concept of electrochemical CO_2 capture and conversion film was successfully demonstrated on a laboratory scale. Bae et al. [98] modified a seawater battery system for desalination and carbon capture. As shown in Figure 7, the system is mainly composed of three compartments: desalination, sodium collection, and carbon capture. The compartments are separated by sodium ion superconducting ceramic membranes. By charging and discharging the system, sodium ions are transferred from the desalination compartment to the carbon capture compartment, and hydroxide (OH^-) ions are formed in the carbon capture compartment at the same time, and the hydroxide (OH^-) ions and Na^+, Ca^{2+}, Mg^{2+} React with CO_2 introduced in the atmosphere to form metal carbonate, to achieve the purpose of capturing CO_2. The biggest shortcoming of this system at present is that the reaction of chlorine analysis is relatively difficult, and silver foil is temporarily used as a collecting electrode.

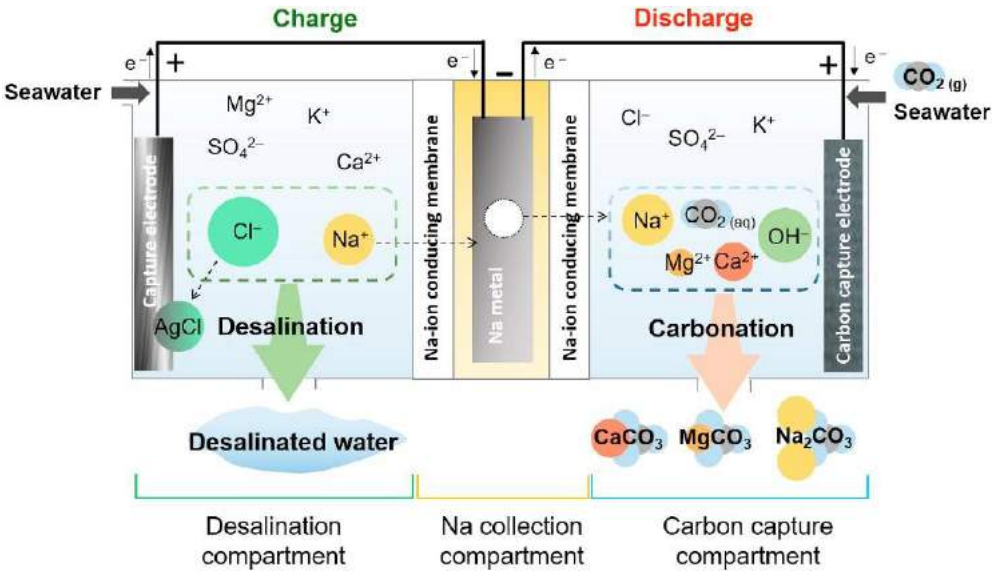

Figure 7. Schematic representation of the hybrid desalination–carbon capture system (SD–CC system). Reproduced with permission from [98], Elsevier, 2019.

3. CO_2 Transport

After the CO_2 is separated from the flue gas, it must be transported to a storage site for storage or a factory for processing and utilization. Regardless of the ultimate fate of CO_2, a safe, reliable and economically viable CO_2 transportation system is a key link in the realization of CCUS technology. At present, the main transportation methods of CO_2 are tanker transportation, pipeline transportation and ship transportation. Different shipping methods are suitable for different shipping situations. Example: A power plant with a design life of more than 23 years that produces CO_2 suitable for pipeline transportation. For some short cycles CO_2 transportation, tanker transportation and ship transportation are more competitive [1]. The amount of CO_2 and the distance between the way of CO_2 capture and the storage location are critical to the choice of CO_2 transport mode. In this section of the review, we will focus on pipeline transportation and ship transportation.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

3.1. Pipeline Transportation Technology

Pipeline transportation is the most economical way to transport large quantities of CO_2. At present, the length of global CO_2 pipelines exceeds 8000 km, and most of these pipelines are located in the United States. However, this length is far from meeting the demand for CO_2 pipeline transportation under the carbon-neutral target, and a large number of CO_2 pipelines need to be built in the future. This section summarizes the research on CO_2 pipeline transportation from three aspects: transportation status and process, pipeline design and flow assurance, and transportation safety and risk [99,100].

3.1.1. Conveying Status and Process

CO_2 has low critical temperature and pressure and is prone to phase changes. Its transport forms include gas transport, liquid transport, dense phase transport and supercritical transport. When multi-phase flows in the pipeline, CO_2 is easy to change phase and causes pipe cavitation, so CO_2 is usually transported in single-phase. Similar to oil and gas pipelines, CO_2 also needs to be supplied with pressure through a compressor or pump to meet the purpose of transmission. Through practice, it is found that gas transportation and liquid transportation are more suitable for short-distance pipelines, and dense phase transportation and supercritical transportation are more suitable for long-distance pipelines. Among them, supercritical transportation and dense phase transportation are more economical [101]. Figure 8 shows the process flow diagram of these four conveying modes.

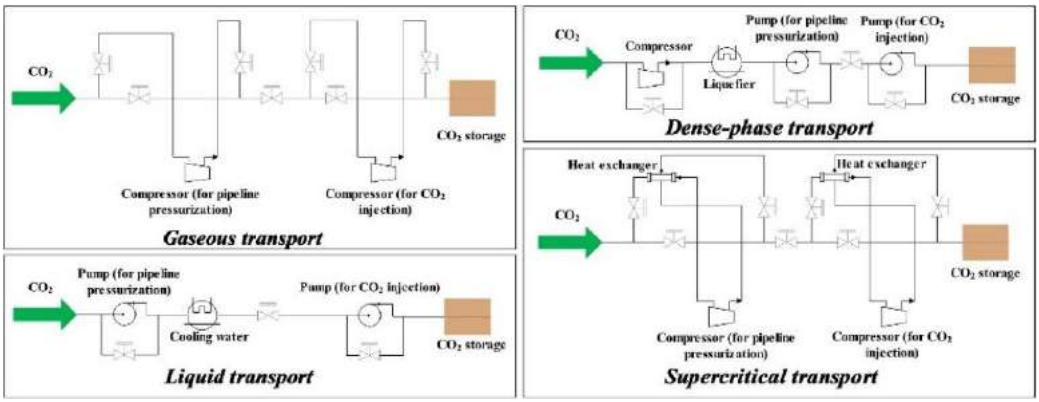

Figure 8. Four process flow charts applicable to large-scale CO_2 pipeline transportation. Reproduced with permission from [101], Elsevier, 2020.

Some scholars and institutions have conducted some research on CO_2 pipeline transportation [102]. Zhang et al. [103] found that the low critical temperature (31.1 °C) of CO_2 is an important feature, and the control system temperature and pressure directly determine the process design and pressure loss of the system. Under favorable climatic conditions, CO_2 transport in the supercooled liquid state can significantly save energy. At the same time, they also found that CO_2 has the largest safe transport distance. Lu et al. [104] determined the flow transmission range of different pipe diameters according to the phase change during the transportation of liquid CO_2. Drescher et al. verified the ability of the Schlumberger flow assurance tool OLGA and SINTEF Energy Research's in-house CFD tool to simulate the decompression behavior of a CO_2 pipeline. Their simulation results are consistent with the experiment. However, OLGA and SINTEF deviate from the experimental results in terms of simulated temperature [105].

3.1.2. Pipeline Design and Flow Assurance

The efficient transmission of CO_2 from source to sink requires the adequate design of the CO_2 transportation pipelines. The length of the pipeline should be minimized when designing the pipeline. Longer pipelines also require larger diameters, which will increase the construction and operation costs of the pipeline. The pipe diameter should not be too

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

small. The pipe diameter determines the transmission capacity. Too small a diameter will cause too high a CO_2 flow rate, increasing pressure loss and corrosion of the pipe wall [106]. Therefore, the most reasonable pipe diameter is the minimum pipe diameter to meet the CO_2 transmission requirements [107]. Mohammadi et al. [108] proposed a cost optimization framework for a CO_2 transportation system and concluded that pipe diameter and horizontal angle are important parameters for pipe design. When designing the CO_2 pipeline, the wall thickness of the pipeline should also be considered. Different transportation modes will also affect the wall thickness design of the pipeline. Teh et al. [109] found that under the same conditions in other cases, the wall thickness required for CO_2 liquid transportation is less than that required for CO_2 supercritical transportation. When the captured CO_2 is stored, differences in potential reservoir capacity and injection capacity may significantly change the economy and design of the CO_2 transport system. Wang et al. [110] proposed a decision tree-based method by analyzing some cases, which can quickly and accurately estimate the best reservoir selection and pipeline design without any optimization.

Temperature and pressure are the key factors to control CO_2 pipeline transportation. Changes in temperature and pressure will change the phase state of CO_2 and affect the normal operation of the pipeline [111]. In recent years, many scholars began to study it. Lu et al. [101] found that under the same operating conditions, the pressure drop of a CO_2 pipeline is lower than that of natural gas pipeline, but its temperature drop is larger, so hydrates are more likely to be generated in a CO_2 pipeline. The existence of impurities will affect the thermophysical properties of CO_2, thus affecting the pipeline transportation of CO_2 [112]. Lee et al. [113] studied the in-tube heat transfer coefficient and compressor power consumption with impurity CO_2. It was found that both the heat transfer coefficient and the compressor power consumption followed the trend of pure CO_2, but were influenced by the type and amount of impurities. Baik et al. [114] studied the pressure drop of CO_2 + CH_4 in the pipe under seawater conditions. With the decrease of CO_2 mole fraction, the average pressure drop in the pipe increases, and the pressure drop of CO_2 + CH_4 increases with the increase of mass flow rate. Teh et al. [109] studied the difference between the transportation of liquid CO_2 and supercritical CO_2 at ambient temperature. The authors believe that as long as the liquid CO_2 pipeline is buried deep enough in the soil with poor thermal conductivity, it does not need to keep the trunk line warm, and the same amount of CO_2 is transported at the same distance. Liquid CO_2 is superior to supercritical CO_2.

3.1.3. Transportation Safety and Risk

At present, most of the existing CO_2 pipelines are located in less densely populated areas, but in the near future, CO_2 pipelines may span densely populated areas. As CO_2 is toxic at a certain concentration, the harm of CO_2 at different concentrations to the human body is shown in Figure 9 [115]. At present, the safety and risk research of CO_2 pipelines mainly includes three aspects: the impact of impurities on CO_2 pipeline transportation, the corrosion of CO_2 pipeline and the accidental leakage of CO_2 pipeline [116].

In the process of carbon capture, due to the different sources and capture methods of CO_2, there are often different types of impurities in the pipeline CO_2 fluid. The allowable limit of impurities in CO_2 depends on the geological conditions of the storage formation or the use specifications [117,118]. The content of impurities is usually very low, but the existence of a small number of impurities will also have an adverse effect on the safe operation of the pipeline [119,120]. Zhao et al. [120] believed that the equation of state is very important for calculating the heat transfer and pressure drop of a CO_2 pipeline. The PR equation of state applies to pure CO_2. For CO_2 mixtures containing impurities, the mixture parameters of the PR equation of state must be determined first. The authors also found that the effect of CH_4, H_2, NO_2 and other impurities on phase equilibrium is different. Peletiri et al. [118] studied the influence of impurities on the flow of CO_2 in the pipeline. The authors found that nitrogen had the greatest influence on the pressure, temperature and other physical parameters of CO_2 in the pipeline, while H_2S had the least

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

influence on CO_2. Wetenhall et al. [121] found that adding NO_2 and SO_2 would reduce the diameter of the pipe in question, and the higher the content of impurities, the smaller the pipe diameter required.

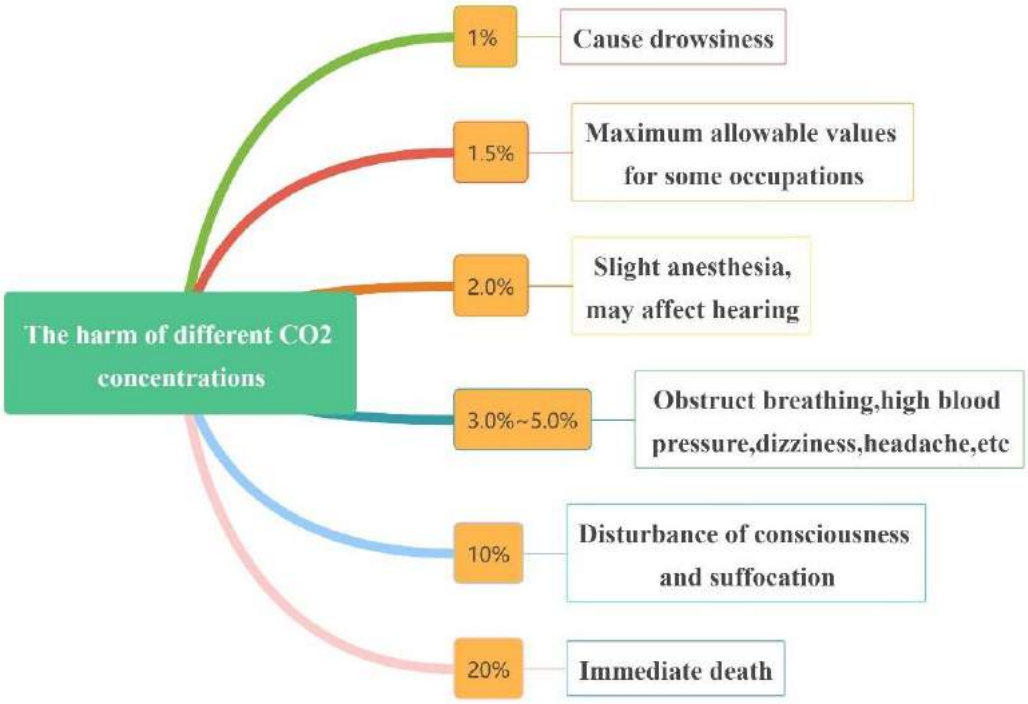

Figure 9. Hazards of different CO_2 concentrations to human health. Reproduced with permission from [101], Elsevier, 2020.

Supercritical CO_2 pipeline is prone to corrosion risk, which affects the safe operation of pipeline [122]. Cui et al. [123] found that water content is the key factor affecting corrosion, and controlling the water content below the critical water content is the most economical and effective method to reduce corrosion. At the same time, the authors also found that among the impurities contained in CO_2, NO_2 had the most serious corrosion effect on CO_2 pipelines. When multiple gas impurities exist at the same time, there will be a synergistic effect, which will have a more serious impact on corrosion. Tang et al. [122] summarized the metal corrosion problems under the combination of various impurities and studied the corrosion mechanism of synergistic effect and the formation mechanism of corrosion products. Sim et al. [124] found that the corrosion mass loss increased with the increase in water concentration, especially when the water concentration was greater than 1000 ppmw.

Pipeline leakage is also a potential risk during pipeline transportation. CO_2 pipeline leakage may cause damage to the surrounding environment, which mainly depends on the total amount of CO_2 released and the concentration reached near the leakage [125]. Herzog et al. [126] simulated the leakage and release process of an onshore high-pressure CO_2 pipeline with CFD. Under the specific conditions for which it is set, the extent of the plume increases with increasing temperature. The height of the plume increases with time and depends on the release pressure and the size of the leak. Within a certain range, the size of the leak hole has a much greater effect on the plume height than the release pressure. Joshi et al. [127] found that after the leakage of the CO_2 pipeline, all solid formations were in the expansion zone, and there were no solid formations in the pipeline. This also avoids the possibility of crack propagation caused by solid polymer in the pipeline. At the same time, the authors also found that 55% of the excessive dense gas concentration was observed near the obstacle compared with the concentration on the flat terrain. Xie et al. [128] found through experiments that supercritical CO_2 showed a highly under-expanded jet structure during the leakage process, and with the increase of the leakage size, the typical structure

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

disappeared. In the process of leakage, the mass loss of supercritical CO_2 is greater than that of gaseous CO_2.

3.2. Ship Transportation Technology

The CO_2 ship transport technology mainly refers to the transport of captured CO_2 to the designated place through a CO_2 carrier. Currently, only four CO_2 carriers are put into operation in the world, mainly for the food service industry. The research on ship transportation technology mainly focuses on its economy. Jung et al. [129] found that the cost of CO_2 transportation by pipeline system in Korean offshore CCS projects is lower. However, with the development of CO_2 carriers, the cost may be lower than that of pipeline transportation. When the distance of CO_2 ocean transportation exceeds 350 km, the cost of ship transportation is lower than that of pipeline transportation [130]. Roussanaly et al. [131] analyzed the transportation costs of CO_2 carriers with pressures of 7 Barg and 15 Barg respectively. The authors found that for all the transportation distance and annual transportation volume combinations considered, 7 Barg transportation has more price advantages.

In a word, CO_2 transport is an important link between carbon capture and storage. Pipeline transport technology and ship transport technology apply to large-scale CO_2 transport. The comparison between these two technologies is shown in Table 3. Although the development of CO_2 transport technology is relatively mature, however, it is still necessary to continue to improve and study the impact of impurities on CO_2 pipelines and the analysis of CO_2 leakage consequences.

Table 3. Carbon Dioxide transportation alternatives [132].

Transporation Method	Conditions	Phase	Capacity	REMARKS
Pipelines	4.8–20 Mpa 283–307 K	gas, liquid, supercritical, dense phase	~150 Mt CO_2/year 8000 km of pipeline transport in operation	• higher capital costs, lower operating costs • low-pressure system is 20% more expensive than dense phase transmission • well-established for EOR USE.
Ships	0.65–4.5 Mpa 221–283 K	liquid	>70 Mt CO_2/year	• higher operating costs, lower capital costs • currently applied in the food and brewery industry for smaller quantities and different conditions

4. CO_2 Utilization

In recent years, the utilization of CO_2 has received more and more attention. The best way to remove CO_2 is to use CO_2 to make valuable products. At present, the global annual CO_2 emissions exceed 32 billion tons, but the CO_2 utilization is less than 200 million tons. From this point of view, the utilization of CO_2 is unlikely to significantly reduce the content of CO_2 in the atmosphere, but people pay more attention to the economic or environmental benefits of the process. Therefore, the utilization of CO_2 is considered a stepping stone for the large-scale implementation of CCUS technology [133–135].

CO_2 can be used in a variety of ways, including technical, biological or chemical. CO_2 can be directly used in energy production to help improve oil recovery, directly used as raw material for chemicals, and directly used as raw material for bioenergy production. CO_2 can also be directly used in the food processing industry. These uses are discussed below [136,137].

4.1. Strengthen Energy Production Technology

Energy such as fossil fuels is the material basis for the survival and development of human society. The traditional fossil fuel recovery technology and recovery efficiency are limited, and the work efficiency is not high. The use of CO_2 in the recovery of fossil fuels can not only effectively improve the recovery rate, but also play a role in CO_2 storage. As shown in Figure 10, CO_2 can be used to exploit oil, natural gas and coal bed methane.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

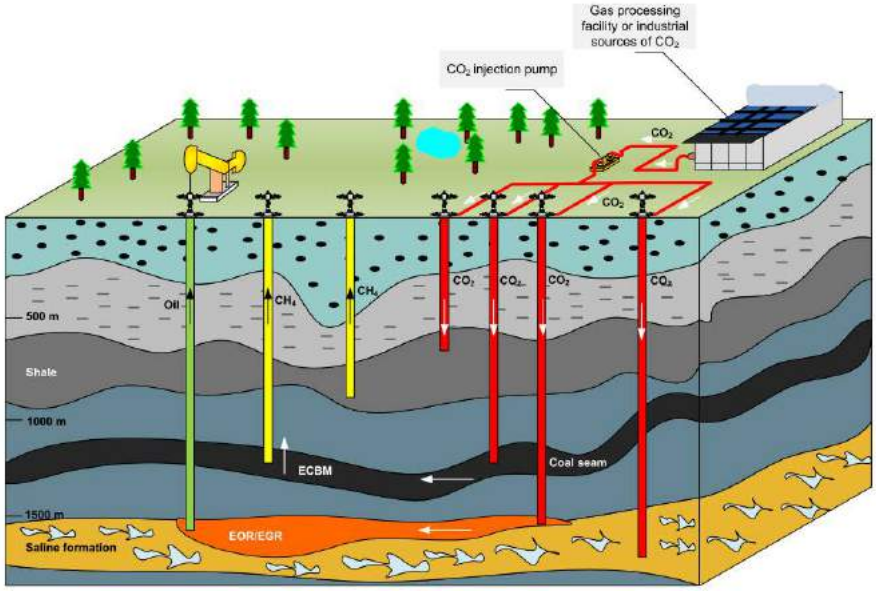

Figure 10. CO_2 enhances energy production [138].

4.1.1. Enhanced Oil Production Technology

It is more and more important for the petroleum industry to enhance the oil recovery (EOR) process. CO_2-enhanced oil recovery technology refers to a technology that uses CO_2 as the oil-displacement medium to improve oil recovery. This technology has been applied for decades. The United States is an early country in the world to study and apply CO_2 flooding technology. Stewart et al. [139] found that in the North Sea oilfield, CO_2 flooding can maximize the production of mature oilfields, and CO_2 flooding can be used to produce low-carbon oil. More than 90% of reservoirs in the world are suitable for CO_2_EOR [135]. In the process of CO_2_EOR, the most important is the mixed phase of CO_2 and crude oil [140]. CO_2 flooding technology mainly includes miscible flooding and immiscible flooding. At present, immiscible flooding technology is rarely used, and the most ideal technology is miscible flooding. Miscible flooding can achieve the highest oil recovery during CO_2 flooding. The minimum miscibility pressure (MMP) is very important for the miscible flooding of CO_2. The lower miscibility pressure is beneficial to the economic operation of CO_2 flooding projects.

CO_2 flooding has become one of the most commonly used EOR methods. Many scholars have begun to study the influencing factors of CO_2 flooding and how to improve the recovery factor of CO_2 flooding. Cao et al. [141] found that in the process of CO_2 immiscible flooding, the oil recovery rate increases with the increase of pressure. When the pressure exceeds the minimum miscible pressure, the oil recovery rate slightly increases and finally stabilizes near a maximum value. The wettability of the reservoir will also affect the recovery factor of CO_2 flooding, and the recovery factor of oil–wet cores is higher than that of water–wet cores [142]. Hamidi et al. [143] studied the effect of ultrasonic-assisted CO_2 flooding on oil recovery. Under an appropriate injection rate, ultrasonic-assisted CO_2 flooding can improve oil recovery. In addition to research on enhanced oil recovery, monitoring downhole and blowdown emissions from CO_2 displacement and strengthening risk management need to be considered. At the same time, we should speed up the construction of the CCUS–EOR technical standard system to promote the rapid and profitable development of the entire industry chain.

4.1.2. Strengthening Gas Production Technology

Enhanced gas production technology mainly refers to injecting CO_2 into a gas reservoir or shale reservoir in supercritical form to enhance gas recovery (CO_2–EGR), while storing CO_2. The key to improving natural gas recovery by CO_2 is to control the miscibility of CO_2

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

and CH_4. CO_2 and natural gas are miscible at any ratio, which will reduce the displacement of CO_2 on natural gas and reduce the recovery of natural gas. At the same time, CO_2–EGR does not apply to all gas fields [144,145]. Gas mixing can be limited by good reservoir management and production control measures [146].

As unconventional natural gas, shale gas has attracted worldwide attention in recent years. As a new shale gas development technology, CO_2 flooding of shale gas is developing rapidly [120]. About 20~80% of natural gas can be stored in shale gas reservoirs in the form of adsorption. The properties, moisture, temperature, pressure and other conditions of shale gas reservoirs will affect the adsorption behavior of CO_2 and CH_4. In reservoirs with more micropores, the preferential adsorption of CO_2 may be higher. When the pressure increases, the preferential adsorption of CO_2 will become weaker [147]. However, the increase in CO_2 injection pressure will increase the recovery of CH_4 and the storage of CO_2 [148]. The CO_2 content in the injected gas also has a great influence on the desorption of natural gas from rocks [149]. When supercritical CO_2 is injected into shale, the porosity and specific surface area of shale will also increase with time and pressure. At the same time, the pore structure and surface chemistry in shale will also change, resulting in a decline in the adsorption capacity of shale for CO_2 and methane [150,151].

During CO_2 flooding of shale gas, the recovery depends on the relative affinity of CO_2 and CH_4 in their mixture. Therefore, the adsorption study of the mixed gas is of great significance for CO_2 flooding shale gas. Song et al. [152] found that the isothermal adsorption capacity of CH_4/CO_2 decreased with the increase in temperature, and the adsorption capacity of CO_2 was greater than that of methane. Qi et al. [147] found that the total adsorption capacity of the CH_4/CO_2 mixture is between two single components. The shape of the isothermal adsorption curve of the mixed gas is similar to that of a single component with a high concentration or strong adsorption affinity. When CO_2 is injected into shale, the interaction between adsorbed gas and the nanopore structure may lead to shale expansion, fracture closure and reduction of permeability of the shale formation [153,154]. Lu et al. [155] found that the increase in CO_2 pressure will make the expansion of shale samples first increase and then decrease. The maximum expansion of shale will gradually decrease with the increase in CO_2 temperature. Strengthening the research on CO_2 adsorption behavior is helpful to the development of CO_2-enhanced gas recovery technology [156].

4.1.3. Technology of Displacing Coalbed Methane

The technique of displacing coalbed methane is to use CO_2 as an adsorbent and inject it into the coal seam to improve the recovery rate of coalbed methane by taking advantage of the characteristic that its adsorption capacity on the surface of the coal body is higher than that of methane (CO_2–ECBM). At present, most CO_2–ECBM projects are implemented in deep coal seams, because the coal in deep coal seams cannot be economically exploited, and the possibility of injected CO_2 returning to the atmosphere is small [157,158]. Displacing shale gas, after CO_2 is injected into coal seams, the pore structure and chemical and physical properties of coal will also change, affecting the effect of displacing coalbed gas [159]. The decrease of coal seam permeability is the main problem in the whole process. The reduction of coal seam permeability will affect the production rate of CH_4, the injection amount and the injection pressure of CO_2. The expansion of coal after CO_2 adsorption is the main reason for this situation [160].

The properties of coal seams and injected CO_2 affect the expansion of coal bodies. The higher the coal grade is, the more favorable it is for CO_2 to displace CH_4 [160]. The increase in coal seam temperature will lead to the increase of kinetic energy of CO_2 molecules and the decrease of CO_2 adsorption capacity, thus reducing CO_2 reserves and CH_4 production [161,162]. Compared with gaseous or subcritical CO_2, supercritical CO_2 is more easily affected by coal seam temperature [163]. With regard to temperature, the combined effects of thermal expansion, thermal cracking and gas phase transition should also be considered [164]. The presence of water in coal seams also significantly affects the

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

adsorption and desorption of CO_2 and CH_4. Water, CH_4 and CO_2 in coal compete with each other in the adsorption position, which affects the effect of displacing coalbed methane. The H_2O molecules on the coal will induce the expansion of the coal matrix, resulting in the reduction of the porosity and permeability of the coal seam. Water molecules trapped in the pores may also block the channel for CH_4 desorption from coal [165–167].

Hou et al. [161] found that the injection pressure of CO_2 affects the displacement and migration rate of CH_4, and increasing the pressure can increase the storage of CO_2 and the recovery of methane. Increasing temperature or pressure will also shorten the adsorption equilibrium time of CO_2 and CH_4 [168]. Perera et al. [169] found that under higher CO_2 injection pressure, pore elasticity will increase porosity, which is more influential than adsorption expansion. However, some scholars found that higher CO_2 injection pressure may also lead to coal matrix expansion, which will reduce the permeability of coal seams, and the reduction of supercritical CO_2 will be greater [160,163]. Therefore, the CO_2 injection pressure should be reasonably determined according to the actual situation of the coal seam. The captured CO_2 usually contains impurities (Such as N_2). Injecting mixed gas (CO_2/N_2) can improve the replacement efficiency of CH_4 and promote the recovery of CH_4 [170–172]. In the process of CO_2 flooding coalbed methane, compared with gaseous CO_2 flow, supercritical CO_2 flow can exchange better with CH_4, and the sweep efficiency of supercritical CO_2 injection is higher, resulting in a longer expansion period. The effectiveness of supercritical CO_2 in CH_4 recovery has nothing to do with the maturity or grade of the coal seam [169,173,174]. The viscosity of gaseous CO_2 increases with temperature, while the change of supercritical CO_2 is the opposite. Because the temperature of the underground coal seam is higher, compared with gaseous CO_2, supercritical CO_2 has a stronger sliding capacity and a shorter contact time with the coal matrix, which reduces its adsorption capacity [162].

4.1.4. Enhanced Geothermal Technology

Geothermal is a good alternative energy. CO_2-enhanced geothermal technology (CO_2–EGS) uses supercritical CO_2 as the heat transfer fluid and uses a method similar to hydraulic fracturing to activate the cracks in the rock so that CO_2 can extract heat from the rock through the rock. Supercritical CO_2 has many advantages. First, it has a large expansion rate and low viscosity, thereby reducing the power consumption of fluid circulation and improving the speed of fluid circulation. Secondly, CO_2 is a non-polar solvent, which will reduce the dissolution of rock minerals and eliminate scaling problems. Finally, CO_2 may be an attractive fluid for heat, so it has advantages in accelerating energy uptake. In the process of geothermal exploitation, attention should also be paid to the influence of CO_2 injection temperature and pressure. Lower CO_2 injection temperature is favorable for thermal extraction [175]. The higher the CO_2 injection rate, the worse the heat transfer effect. Therefore, when the CO_2 injection rate is high enough, the heat transfer between the wellbore and the surrounding reservoir can be ignored, thus extending the service life [176]. The nature of the reservoir will also affect CO_2–EGS. Wang et al. [177] found that lower reservoir permeability and initial reservoir temperature are more favorable for CO_2–EGS. And with the increase of formation permeability, the efficiency of heat extraction increases, but the rate decreases. The rock chemical and mechanical interaction caused by supercritical CO_2 in the pores will affect the flow behavior, change the porosity and permeability of the reservoir, and affect the energy extraction process, but the current research in this field is less [178].

4.2. Chemical Conversion Technology

CO_2 chemical conversion technology mainly uses CO_2 to produce fuels and chemicals, which can provide additional value and may store CO_2 [179]. Due to the thermodynamic stability and kinetic inertia of CO_2 molecules, the direct synthesis of CO_2 usually has the disadvantages of low synthesis efficiency and harsh reaction conditions. At present, only a few chemicals in industry are made of CO_2. Although the utilization potential of CO_2 as a

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

chemical raw material is limited, it can reduce the dependence of the chemical industry on traditional fossil fuels. Table 4 is an example of chemicals currently used for CO_2 synthesis at the pilot scale as summarized by Burkart et al. [134]. In the following section, we will introduce some CO_2 conversion methods and their future challenges.

Table 4. Selected examples of chemicals currently synthesized from CO_2 on a pilot plant scale. [a] Reproduced with permission from [134], American Chemical Society, 2019.

Chemical	Company (Location)	Scale Per Year [b]
Carbon monoxide (via SOEC) [c]	Haldor-Topsoe (Lyngby, Denmark)/ Gas Innovations (La Porte, TX, USA)	12 Nm^3/h
Methanol	Carbon Recycling International (Reykjavík, Iceland) Mitsui Chemical Company (Tokyo, Japan)	4000 tons 100 tons
Methane	Audi (Ingolstadt, Germany)	1000 tons
Fuels (via CO_2-based Fischer-Tropsch)	Sunfire (Dresden, Germany) INERATEC (Espoo, Finland)	3 tons 200 L
Oxalic acid	Liquid Light/Avantium (Amsterdam, The Netherlands)	2.4 tons

[a] A pilot plant is defined as a pre-commercial system, which produces a chemical or fuel on a smaller scale than a full plant and is used for learning purposes. [b] Amount of product that is produced per year. [c] SOEC = solid oxide electrolyzer cell.

4.2.1. Raw Materials for the Chemical Industry

At present, scholars and institutions around the world have developed many chemical routes for CO_2 utilization. Most of these routes only consider the possibility of synthesis and do not consider the reduction potential or potential profitability of CO_2. The direct conversion of CO_2 is mostly to reduce CO_2 to CO through reverse water gas shift (RWGS) reaction, and then to hydrogenate CO to the required chemicals [180]. Otto et al. [181] evaluated 123 reaction routes of CO_2 conversion into chemicals. The authors selected the types of these reactions that can meet the standards based on the potential of reducing the amount of CO_2 and the economic benefits of synthesis. Among the six selected bulk chemicals (methanol, formaldehyde, formic acid, oxalic acid, urea and dimethyl ether), five of them are CO_2 and H_2 reactions. Therefore, CO_2 catalytic hydrogenation is the most potential technology and the technology most likely to be applied on a large scale in a short term. Figure 11 shows the different transformation routes of applying renewable energy to CO_2 hydrogenation. Kondratenko et al. [182] analyzed the current situation of converting CO_2 into chemicals through catalytic hydrogenation, photocatalysis and electrocatalysis. Among them, the catalytic hydrogenation of CO_2 to methanol and methane has formed a commercial scale, while electrocatalysis and photocatalysis still require significant technological and catalytic progress [183]. At the same time, the authors also mentioned that the most critical problem of catalytic hydrogenation is the need for cheap and clean H_2. This is also the development trend of CO_2 catalytic hydrogenation in the future. Although the large-scale application of CO_2 electrocatalysis technology still faces challenges, with the development of technology, it is considered to be one of the most promising technologies in the future. Many researchers have proposed various methods to promote the development of electrocatalysis technology, such as increasing active sites on electrodes, using alloy catalysts, etc. [184–186]. Park et al. [185] believed that low productivity and product separation difficulties caused by low current density and Faraday efficiency were the main factors hindering the large-scale application of electrochemical conversion. However, by introducing cutting-edge equipment (zero gap electrolytic cells, etc.), large-scale application of electrochemical conversion can be possible. In addition, the lack of in situ observation of the reaction mechanism and active sites during electrocatalytic experiments also hindered its development. Coupling electrocatalytic technology with renewable energy is an important development direction in the future.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

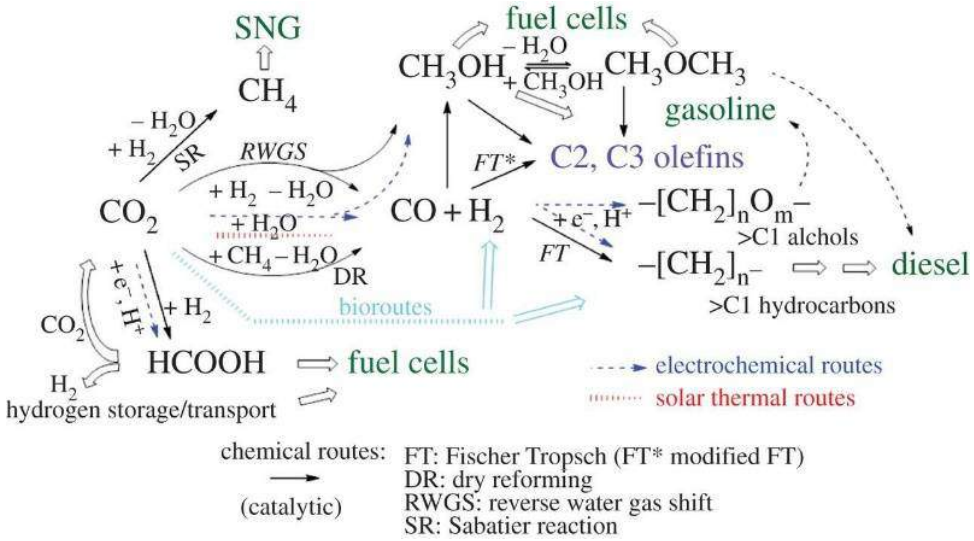

Figure 11. Possible routes for CO_2 hydrogenation with the incorporation of RE in the process. Reproduced with permission from [187], Royal Society of Chemistry, 2015.

In order to utilize CO_2 efficiently, catalysts are usually used to reduce the activation energy during the chemical conversion of CO_2 [188,189]. At present, research on CO_2 catalytic reduction focuses on the formation of C1 products. Different C1 products are controlled by the reduction degree, which is also a major challenge [134]. The preparation method of the catalyst usually affects its specific surface area, particle size, metal dispersion and other properties, thus affecting the activity and selectivity of the catalyst [190]. Therefore, an appropriate preparation method must be selected when preparing the catalyst [191]. Doping and alloying of foreign atoms can change the surface morphology of the catalyst, which is an effective method to improve the activity and selectivity of the catalyst [186]. At present, the price of catalysts is relatively expensive, and the conversion rate is not high, continuous and stable production is difficult, so the future needs more in-depth research.

For renewable energy, the utilization of CO_2 is a great opportunity to help it inject into the chemical production process [187]. At the same time, renewable energy sources such as wind energy and solar energy have shortcomings such as intermittency and anti-peak shaving, and their introduction into the CO_2 conversion process is considered to be an ideal method for efficient electric energy storage and conversion [186]. As shown in Figure 12, CO_2 photocatalytic conversion is to convert CO_2 into valuable products by using renewable energy (solar energy) under mild reaction conditions. This process will not pollute the environment and does not require additional energy [192]. Titanium dioxide is the most commonly used catalyst in photocatalytic reactions, but it also has its limitations, such as low efficiency and activity of the catalyst. This problem can be effectively solved by doping, semiconductor coupling, cocatalyst modification, design of photo reactor and other methods [192–195]. If the price of renewable energy continues to fall, it will be possible to use renewable energy for CO_2 use through catalytic methods in the future.

The use of CO_2 for fuel production can reduce the use of traditional fossil fuels. This process usually requires a reforming reaction, such as reforming CO_2 and CH_4 to produce synthesis gas. At present, dry reforming (DRM), partial oxidation (PO) and steam reforming (SRM) have been proposed for reforming methane to obtain syngas. The reaction equations of the three methods are as follows:

$$\text{DRM: } CH_4 + CO_2 \rightarrow 2CO + 2H_2 \ \Delta H_{298K} = +247 \text{ KJ/mol} \quad (1)$$

$$\text{PO: } CH_4 + \frac{1}{2}O_2 \rightarrow CO + 2H_2 \ \Delta H_{298K} = -22.6 \text{ KJ/mol} \quad (2)$$

$$\text{SRM: } CH_4 + H_2O \rightarrow CO + 3H_2 \ \Delta H_{298K} = +228 \text{ KJ/mol} \quad (3)$$

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

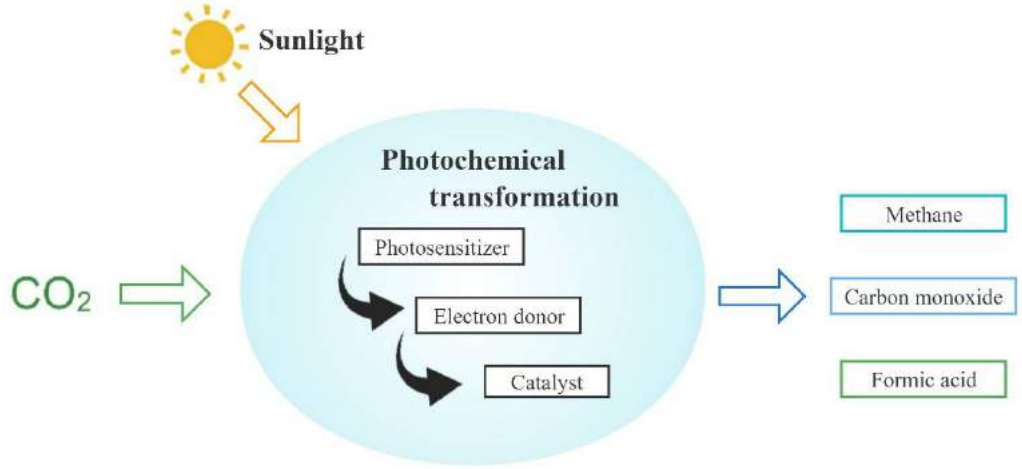

Figure 12. Mechanism of photochemical transformation of CO_2. Adapted with permission from [192], Elsevier, 2019.

It can be seen from the reaction formula that the oxidant used in the three methods is different, and the oxidant used in DRM is CO_2. Therefore, it is considered to be the most promising technology [136]. However, DRM is a highly endothermic reaction that needs to be carried out at high temperatures. Therefore, it may induce CH_4 decomposition, CO disproportionation and other side reactions, leading to coke deposition, adsorption on the catalyst surface, and ultimately leading to catalyst deactivation and reduction of conversion [196]. The formation of coke can be reduced by controlling the reaction temperature and feed ratio [197]. Aramouni et al. [198] believed that bimetallic catalysts formed by adding a small amount of precious metals or other non-precious metals to cheap non-precious metals can show good performance in catalysis. This can not only overcome the shortcomings of rapid deactivation of non-precious metals and high coke but also reduce the price of catalysts. At the same time, the authors think that Co–Ni bimetallic catalyst has great development potential in the future. The reforming of CO_2 and methane is not only affected by the catalyst, Ayodele et al. [199] found that the partial pressure of reactants ($CO_2 + CH_4$) will also have a great impact on conversion, yield and gas production ratio. Although DRM is considered a technology with environmental potential, its development is limited by its extremely high reaction temperature, long reaction time, requirements for pure CO_2 and catalyst deactivation [136].

CO_2 can also be used to produce biofuels such as methanol (CH_3OH) and dimethyl ether (CH_3OCH_3). Methanol is widely used in various chemical industries. Although compared with gasoline, its energy content is low. However, due to its excellent cooling effect and extremely high anti-knock ability, it is suitable for vehicles driven by internal combustion engines [133,200]. At present, methanol production by CO_2 hydrogenation catalysis is the most studied, and its reaction formula is shown in (4):

$$CO_2 + 3H_2 \rightarrow CH_3OH + H_2O\ \Delta H_{298K} = -49.5\ KJ/mol \quad (4)$$

Although it has good thermodynamic properties, it still needs to use appropriate catalysts to overcome the obstacle of high activation energy. At the same time, a highly selective catalyst should be used in the reaction process to avoid generating other hydrogenation products (such as higher alcohols) [201]. In methanol synthesis, the efficiency of using a Cu catalyst alone is not high, while the supported Cu-based catalyst shows a strong loading effect. Cu/ZnO catalysts have been widely studied for CO_2 hydrogenation to methanol [202]. ZnO can not only enhance the adsorption of CO_2 on the surface of Cu but also promote the dispersion of copper, thus improving the reactivity of Cu [203]. Kattel et al. [204] studied the active sites on the Cu/ZnO catalyst. They believed that the surface oxidation of ZnCu alloy occurred during methanol synthesis, which oxidized the

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

surface Zn to ZnO, making the activity of ZnCu and ZnO/Cu the same under the same Zn coverage. The addition of oxides to the Cu/ZnO catalyst can effectively improve the performance of the catalyst. The most commonly used oxide is Al_2O_3 [205]. Due to the rich oxygen utilization rate and good ion exchangeability of the ZrO_2 surface, it is also often studied for binding with Cu/ZnO. The hydrophilicity of ZrO_2 is weaker than that of Al_2O_3, which can improve the dispersion and stability of Cu. In addition, ZrO_2 can increase the alkalinity of the catalyst, which is conducive to improving the selectivity of the catalyst [206]. In addition to improving traditional Cu/ZnO-based catalysts, many scholars are also developing new catalytic systems [207].

Dimethyl ether (DME) is also widely used in the chemical industry, and it is also an effective substitute for fossil fuels. In addition, it produces less NO_x, SO_x and particulate matter during combustion, which has little environmental pollution. At the same time, its cetane number is higher than that of methanol, so it is more suitable as a substitute for diesel [208]. DME is usually produced by indirect synthesis and direct synthesis, as shown in Figure 13. Indirect synthesis is to first synthesize methanol through synthesis gas and then dehydrate methanol to produce dimethyl ether. The reaction equations are shown in (5) and (6). Direct synthesis is catalyzed by CO_2 hydrogenation, and the reaction formula is shown in (7).

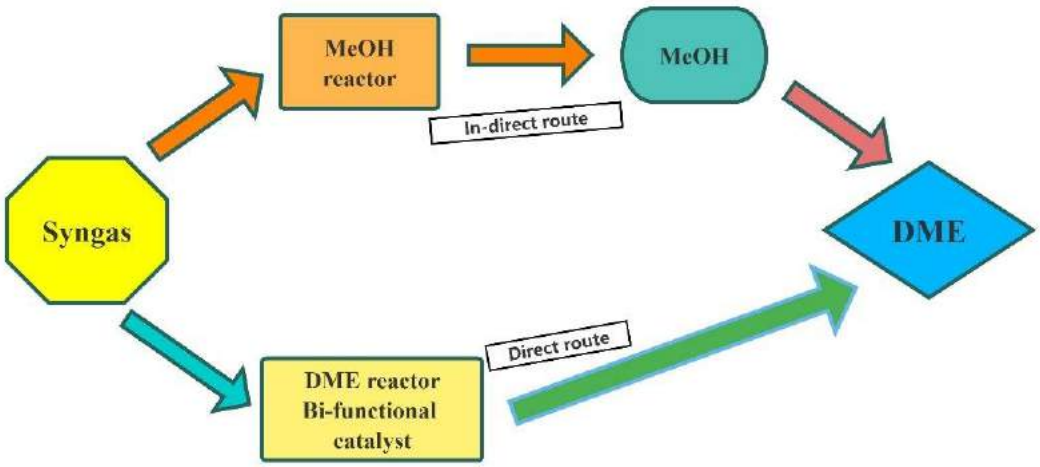

Figure 13. Two pathways for DME production: direct and indirect. Adapted with permission from [209], Elsevier, 2018.

Methanol synthesis:

$$CO + 2H_2 \rightarrow CH_3OH\ \Delta H_{298K} = -93.6\ KJ/mol \quad (5)$$

Methanol dehydration:

$$2CH_3OH \rightarrow CH_3OCH_3 + H_2O\ \Delta H_{298K} = -23.4\ KJ/mol \quad (6)$$

Direct synthesis of dimethyl ether:

$$2CO_2 + 6H_2 \rightarrow CH_3OCH_3 + 3H_2O\ \Delta H_{298K} = -122.2\ KJ/mol \quad (7)$$

Chen et al. [210] studied the reaction characteristics of the indirect synthesis of DME. The indirect method is to produce methanol through synthesis gas, and there is inevitably CO_2 in the synthesis gas. The authors found that the existence of CO_2 would reduce the yield of DEM. Therefore, CO_2 should be separated before synthesis, but this will increase the cost of DEM manufacturing. Samimi et al. [211] proposed a new two-stage spherical reactor based on methanol dehydration to dimethyl ether, aiming at reducing pressure drop and recompression cost and increasing dimethyl ether yield. Compared with the traditional reactor, the reactor can effectively improve the yield. However, the industry

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

generally prefers to use a single-pot synthesis technique for dimethyl ether synthesis to reduce production costs [212]. Chen et al. [213] conducted thermodynamic analysis on the direct synthesis process and indirect synthesis process of dimethyl ether and studied the effects of two different methods on the synthesis of dimethyl ether. The authors think that direct synthesis has a lower thermodynamic limit and is more suitable for the synthesis of dimethyl ether. Zhang et al. [214] used Aspen Plus to simulate the direct syngas to DME synthesis coupled with tri-reforming reactions. The tri-reforming can maximize the use of CO_2 and reduce the use of external energy. The system is most favorable for operation under low temperature and high pressure. Through simulation, the authors find that this process is an economical and feasible method to utilize CO_2.

CO_2 can not only be reformed with methane to produce syngas but also be directly hydrogenated to produce methane. The reaction formula is shown in (8).

$$CO_2 + 4H_2 \rightarrow CH_4 + 2H_2O\ \Delta H_{298K} = -252.9\ KJ/mol \quad (8)$$

Compared with other CO_2 conversion methods, CO_2 methanation has many advantages. It can directly use existing natural gas pipelines for transportation. As far as thermodynamics is concerned, CO_2 methanation is the most favorable, so this reaction is much faster than other CO_2 conversion reactions. Sahebdelfar et al. [215] studied the thermodynamic equilibrium analysis of CO_2 methanation. The results show that CO_2 methanation has a high conversion rate at a low temperature of 200~300 °C. Above 350 °C, equilibrium conversion can be achieved by using the most advanced catalyst, which shows the potential and importance of catalyst improvement. Ni-based catalyst is the most frequently studied catalyst in CO_2 methanation. Because of its low price, it has more commercial value. Tada et al. [216] performed CO_2 methanation on four supports, CeO_2, α-Al_2O_3, TiO_2, and MgO (all containing 10% metallic Ni), and observed their effects on CO_2 conversion rate and CH_4 selectivity. It can be seen from Figure 14 that compared with other catalysts, Ni/CeO_2 catalyst has a higher CO_2 conversion rate, and its selectivity to CH_4 is close to 1 at a low temperature (250~400 °C). Graca et al. [217] studied CO_2 methanation over catalysts containing Ni and Ce supported on HNaUSY zeolite. The authors found that the performance of the catalyst was better with the increase of Ni content, and the presence of Ce further improved the activity and selectivity of the catalyst. In recent years, many researchers have developed a new dual-functional material (DFM) that combines adsorption and methanation functions for the co-capture and methanation of CO_2. This material can combine the two processes of CO_2 adsorption and hydrogenation in a single reactor [218]. Although the reaction of CO_2 methanation is simple, the reaction mechanism is difficult to establish. Even for CO methanation, there is still no consensus on the kinetics and mechanism [219].

4.2.2. Mineralization

The mineralization of CO_2 is not only an effective way of utilization but also can effectively fix CO_2. Both natural silicate ores and alkaline solid waste can be used for CO_2 mineralization. However, the use of natural ores for CO_2 mineralization is costly and challenging [220]. In contrast, the use of alkaline solid waste for mineralization has become an attractive approach. Because it has high reactivity and inherent alkalinity and is easy to obtain. Common alkaline solid wastes include steel slag, cement and concrete waste, etc. Accelerating CO_2 carbonization by using alkaline solid waste can not only capture CO_2 efficiently from industrial flue gas but also form various products, such as $CaCO_3$ and $MgCO_3$. As shown in Figure 15, $CaCO_3$ and $MgCO_3$ can be widely used in cosmetics, pharmaceuticals, construction, paper making and other industries. This can not only solve the problem of alkaline solid waste treatment but also make effective use of CO_2 [221]. Recently, the use of steel slag for CO_2 mineralization has aroused great research interest. Among many alkaline solid wastes, steel slag has the highest CO_2 storage potential [222]. Ukwattage et al. [223] studied the influence of CO_2 pressure, temperature and water–solid ratio on the CO_2 mineralization of steel slag. The authors found that the higher the CO_2 pressure, the faster the carbonization, and the more water in the reactor, the better the sealing effect. At the same time, the temperature has a dual effect, and about 50 °C is the optimal temperature for the reaction system. The National Academy of Sciences believes that mineral carbonization is one of the effective methods for CO_2 utilization, because of its large scale, energy saving and thermodynamic advantages. Through life cycle analysis (LCA), it was found that mineral carbonization can effectively reduce net CO_2 emissions [224]. The process of CO_2 mineralization requires grinding, heating and slurry stirring, which consumes a lot of energy. In the future, the energy in the exothermic reaction should be recovered to compensate for the energy consumption in the process of CO_2 mineralization, to make the CO_2 mineralization economical.

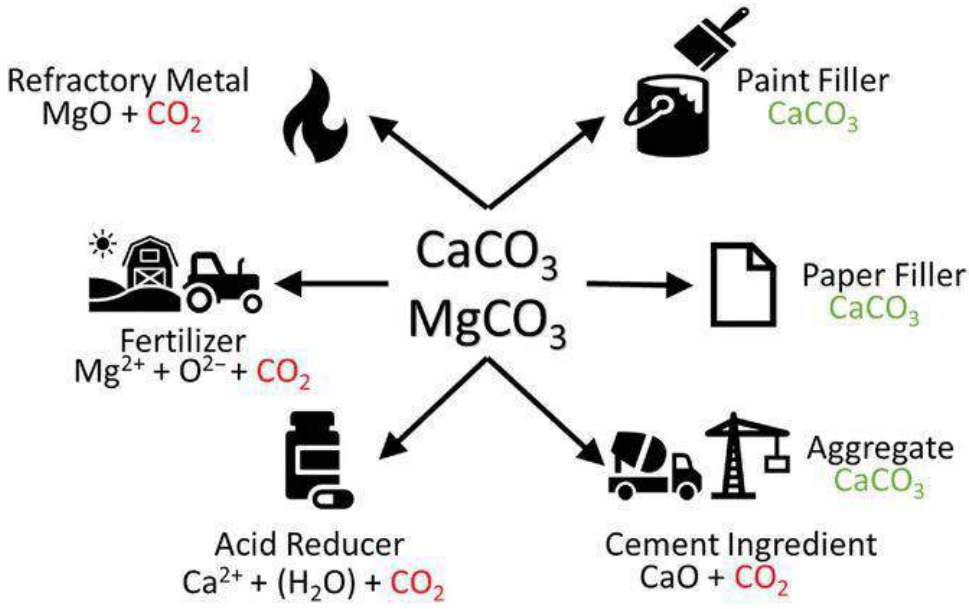

Figure 15. Current industrial uses of carbonate minerals and their final chemical form. From Reference [224].

4.3. Biological Utilization Technology

CO_2 mineralization and CO_2 biological utilization technology can not only effectively utilize CO_2, but also achieve CO_2 fixation. It mainly uses plants or autotrophic microorganisms to convert CO_2 into useful products under specific conditions. Among them, microalgae have attracted great attention. 1 kg algal biomass can fix about 1.83 kg CO_2 [11]. We have introduced the advantages of microalgae in Section 2. It can be used to capture CO_2

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

and grow in a CO_2-rich environment. The harvested algal biomass can be used to produce biofuels. It is considered a substitute for fossil energy and can alleviate the global energy crisis. Figure 16 shows the process required to convert microalgae into biofuel. Different methods can be used to convert microalgae into biofuel (such as biodiesel, bioethanol, etc.) [225]. Biomass can be selectively converted into different biofuels according to their quality and composition. For example, sugar-rich biomass is suitable for the production of bioethanol, and saturated lipid-rich biomass is suitable for the production of biodiesel [209]. However, from the current research results, it is uneconomical to use microalgae to produce biofuels. This is mainly because a large amount of energy is required in the process of extracting lipids from algae cells and transesterification. Algal culture is one of the focuses of research. Culture temperature, CO_2 concentration, salinity, light and pH value will affect the process of CO_2 fixation by microalgae [11,226]. Different microalgae species are suitable for different environments. ArunK. Vuppaladadiyam et al. [227] believed that the CO_2 fixation rate of microalgae was too low, and it was necessary to improve the CO_2 absorption rate or use cheap photobioreactors to compete with mature CCS technology. Otherwise, cultured microalgae are more suitable for conversion into biofuels or chemicals. Bioutilization technology also includes bioelectrochemical systems (BES) [228]. Its essence is to use microorganisms as catalysts to conduct synthesis reactions in the electrochemical cell. Compared with chemical catalysts, biocatalysts have higher specificity and versatility [229]. One possible application of the bioelectrochemical system is the electrochemical reduction of CO_2 to methane, but there are still many challenges [230]. In recent years, the absorption-microalgae composite CO_2 capture technology has attracted more attention, because it can overcome the key challenges of high regeneration energy consumption and low CO_2 concentration in the microalgae solution. Future research should focus on the combination of alkaline solution absorption and microalgae transformation synergistic mechanism [84].

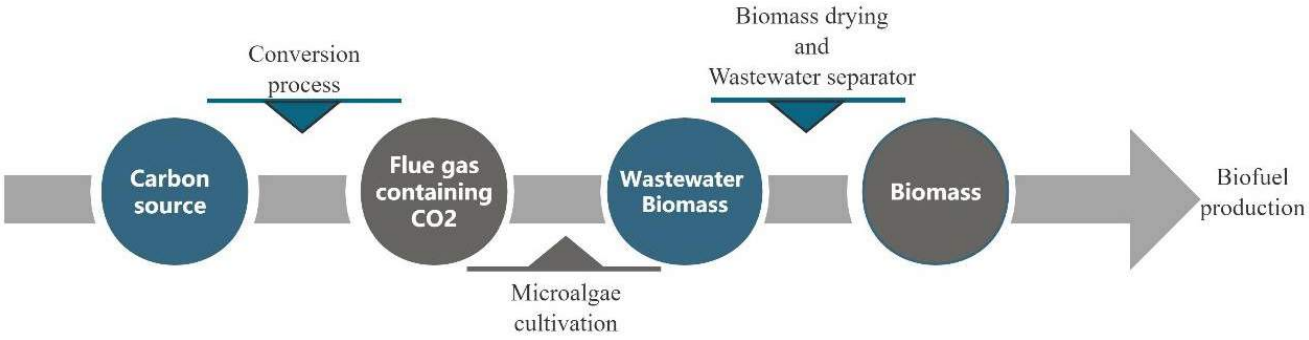

Figure 16. Biofuels from microalgae process. Adapted with permission from [136], Taylor & Francis, 2019.

4.4. Beverage and Food Processing

Food-grade CO_2 is mainly used to produce carbonated beverages, deoxidized water, dairy products and food preservation. Liquid CO_2 and dry ice are mainly used for the preservation of foods that need freeze-drying. The production of beer, soft drinks and sparkling wine will also consume a large amount of liquid CO_2 [11]. CO_2 can also be used as a solvent to extract hops, decaffeinate coffee and tea, and extract spices and essential oils from plant materials. Compared with traditional solvents, CO_2 as a solvent has many advantages, such as being non-toxic, highly stable, low cost, renewable, easy to prepare, etc. Moreover, the amount of CO_2 used as a solvent is less than that of a conventional solvent. [136] Conde-Hernandez et al. [231] compared three extraction methods of rosemary essential oil, steam distillation, hydro distillation and supercritical CO_2, and found that supercritical CO_2 extraction had higher antioxidant activity and oil yield. ZuKnik et al. [232] optimized some parameters (such as temperature, pressure, flow rate and extraction time) in the process of supercritical CO_2 extraction of lycopene to improve the yield of lycopene. Finally, CO_2 can also be used for sterilization. Traditional hot pasteurization will affect the nutritional value and color of food. More and more scientists have begun to study

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

non-thermal pasteurization technology, and high-pressure CO_2 (HPCD) is one of them. It can be carried out at a temperature lower than that of traditional heat treatment. The germicidal efficacy of HPCD has been extensively tested on various microorganisms, so this process can be applied to the food industry. However, the lack of research on its impact on food quality hinders its development [233].

5. CO_2 Storage

CO_2 storage technology is essential to mitigate global warming. It is the best option for reducing atmospheric CO_2 in the short to medium term. IPCC (2014) estimated that 5000~10,000 million tons of CO_2 must be captured and stored every year by the middle of this century. CO_2 storage can be simply divided into geological storage and marine storage.

5.1. Geological Storage

In Section 3, it was stated that CO_2 can be used to improve the recovery of oil, natural gas and coalbed methane, and injected CO_2 can be permanently stored there. In addition, depleted oil and gas reservoirs can also be directly used to store CO_2, but this will not produce economic benefits. The geological storage of CO_2 is the main storage method of CO_2 at present. As shown in Figure 17, geological storage sites mainly include depleted oil and gas field reservoirs, deep saltwater layers and non-exploitable coal seams. Depleted oil and gas reservoirs are considered to be the best storage sites for the following reasons: (i) some existing infrastructure can be utilized, including injection wells and pipelines, etc.; (ii) the oil and gas reservoir itself has good sealing property and can store CO_2 for a long time; (iii) CO_2 can help enhance oil recovery. Saltwater layer storage also has its unique advantages, such as more CO_2 stored, more economical storage process, wide distribution, etc., which is considered to have the largest CO_2 storage potential. The technologies involved in the storage process include a comprehensive survey, site selection, potential evaluation, drilling technology, injection technology, numerical simulation technology, monitoring technology, CO_2 escape plugging technology and safety risk assessment. The development of these technologies can better optimize injection strategies, evaluate reservoir capacity, predict CO_2 migration and diffusion, reduce uncertainty and manage leakage risks [234–236].

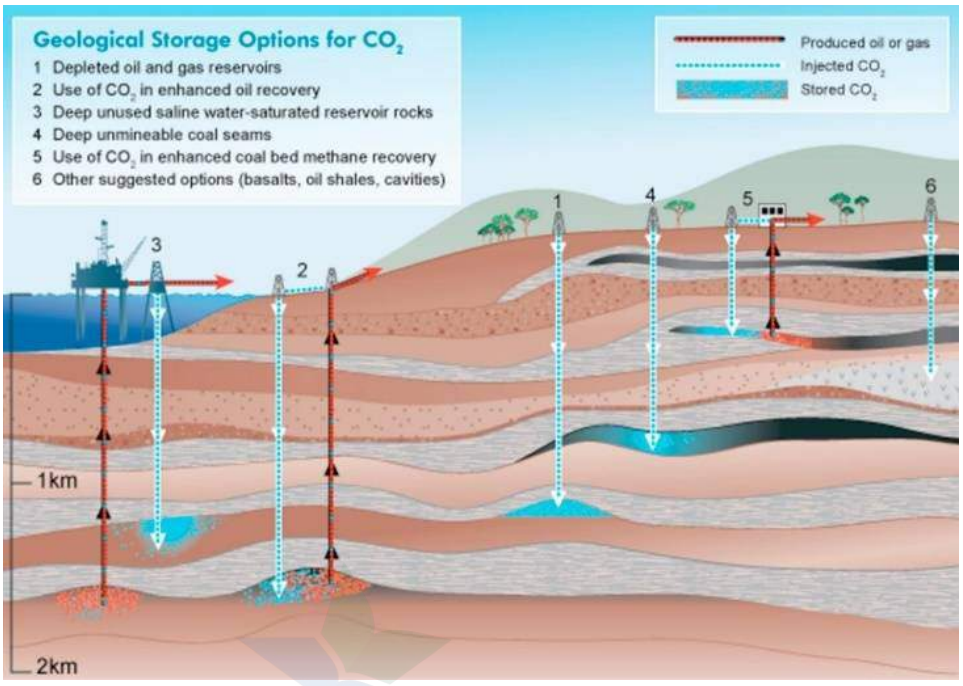

Figure 17. Some geological storage options for CO_2. Reproduced with permission from [237], Elsevier, 2017.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Before geological storage, the storage site must be carefully selected. A good storage site generally includes: sufficient porosity and thickness, tight and complete cap rock, good injectability and stable geological environment, etc. [238] During saline aquifer storage, the location of the aquifer is equally important to the storage process. Too shallow may cause CO_2 leakage. Too deep will increase the injection pressure of CO_2, thus increasing the cost. The chemical composition of aquifer water and formation rock also varies with the location of the aquifer. This will affect the chemical reaction of CO_2 in the aquifer and then affect the mineral structure. At present, the research on CO_2 geological storage mainly focuses on the storage mechanism, storage potential evaluation and storage numerical simulation, and there is less research on the selection of geological storage areas. This is because the selection of the storage site is not easy, and there are many factors to consider. Lu et al. [239] based on the site selection for CO_2 storage in the Ordos Basin of China, determined the favorable and candidate areas for CO_2 geological storage by comprehensively considering technology, safety, reservoir and other aspects. At the same time, the authors also put forward the site selection and sequencing method of CO_2 geological storage, which provides a reference for the selection of CO_2 geological storage in carbonate reservoirs. Hsu et al. [240] developed a multicriteria decision-making model with eight evaluation criteria to select CO_2 storage sites and applied the ANP method to this for the first time. This method can rank potential CO_2 storage sites and be used for pre-screening of CO_2 geological storage sites. Mi et al. [241] analyzed the factors affecting CO_2 storage based on the characteristics of the Junggar Basin in China and established an adaptability evaluation index system for CO_2 storage. At the same time, the adaptability of CO_2 geological storage in the Junggar basin is being evaluated by combining AHP and a fuzzy comprehensive evaluation method. Through the evaluation results, the location with the best suitability is determined.

There are also many mechanisms involved in CO_2 geological storage, and the effectiveness of the CO_2 storage mechanism determines the efficiency of geological storage [242]. The geological storage of CO_2 is affected by many factors, such as temperature, pressure, CO_2 injection rate, the salinity of formation water, mineral composition of formation rock, formation thickness, formation dip, contact angle, interfacial tension and porosity, etc. The higher the pressure, the higher the solubility of CO_2 in brine. This is mainly because the higher the pressure, the greater the thrust. The higher the temperature, the lower the solubility of CO_2 in the brine. This is mainly because the higher temperature provides the system with heat energy. When it overcomes the bond energy between CO_2 molecules and brine molecules, the solubility of CO_2 starts to decrease [243,244]. Wildenschild et al. [245] found that a lower CO_2 injection rate can store more CO_2. Jing et al. [246] found that the CO_2 storage is inversely proportional to the formation dip. At the same time, the larger the dip angle is, the more obvious the influence on CO_2 migration distance is. Because accelerating the dissolution of CO_2 in brine can reduce the risk of leakage, some scholars have proposed some new technologies to accelerate the dissolution of CO_2 [247]. Hassanzadeh et al. [248] proposed a method to accelerate the dissolution of CO_2 in brine. This method can increase the dissolution fraction of CO_2 in 200 years from 8% to 50% by injecting salt water into the top of CO_2.

As shown in Figure 18, when CO_2 is injected into the reservoir for the first time, the risk of leakage is very high. When storing CO_2, the main problem is to consider the potential leakage during injection and whether CO_2 will leak over time. Therefore, when CO_2 is stored for a long time, the caprock must have good sealing capacity. The low permeability of the caprock is critical to prevent CO_2 leakage [237]. When CO_2 leaks, CO_2 itself will not affect the quality of groundwater, but the dissolution of CO_2 will reduce the pH value of groundwater, thus enhancing the dissolution of minerals. Some minerals contain harmful trace elements, which may affect the quality of groundwater [249]. When storing CO_2 in the saltwater layer, the chemical reaction of CO_2 dissolution in the formation fluid and the interaction of CO_2 water rock should also be considered [250]. Jayasekara et al. [250] believed that one of the main problems of saline water reservoir storage was that the cap

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

rock degradation and change caused by geochemical reaction led to the activation of faults and fractures, which led to the reverse migration of injected CO_2 through the cap rock.

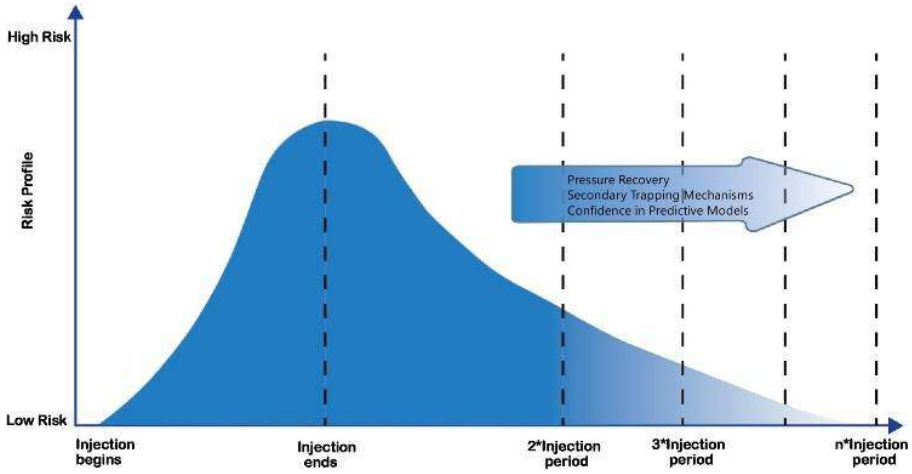

Figure 18. Conceptual risk profile of CO_2 storage in geological porous media. Reproduced with permission from [251], Elsevier, 2021.

Some monitoring technologies can be used to monitor and predict the potential migration path and escape point of CO_2, so as to prevent CO_2 leakage. Geophysical and geochemical methods are widely used in CO_2 leakage monitoring [252]. Among the geophysical methods, the geoelectric method is often used to monitor CO_2 migration, because the subsurface resistivity is affected by CO_2 [253]. Using 4D (delayed) seismic data is the most reliable method to determine the migration mode of CO_2 in the reservoir and can be used to track the evolution of CO_2 plumes [1,251]. Pressure monitoring during CO_2 injection and storage is a key tool. During the injection process, pressure monitoring combined with InSar technology can effectively monitor the leakage of CO_2 into the caprock [236]. Zeidouni et al. [254] proposed a leak detection and characterization method through pressure monitoring. They first gave the relationship between the pressure change of the upper aquifer and the leakage parameters. Then monitor the pressure of the upper aquifer through the monitoring well, and analyze the pressure response caused by the leakage to locate and characterize the leakage. At the same time, more accurate information can be obtained by increasing the number of monitoring wells. Zeidouni et al. [255] studied the feasibility of CO_2 leakage detection by monitoring temperature changes. The authors found that the temperature will increase when the brine leaks, while the temperature will decrease when the CO_2 leaks. Therefore, the leaking fluid can be distinguished by monitoring the temperature change. The strength of the temperature signal is affected by the leakage speed. Reducing the leakage speed will reduce the strength of the temperature signal. At the same time, the temperature change caused by the leakage only covers a small area around the leakage path, so temperature monitoring along the potential leakage path is most useful. Isotopes are also used for monitoring CO_2 leakage, which can detect low level CO_2 leakage [256]. Magnier et al. [257] found that carbon isotopes in some reservoirs are not enough to track CO_2 leakage on the surface, and they found that inert gas is more suitable for monitoring leakage. Remote sensing technology can also be used to monitor CO_2 leakage, commonly used to measure surface deformation, temperature anomaly and vegetation damage [258].

5.2. Ocean Storage

The ocean can absorb a large amount of CO_2 through the natural exchange between water and the atmosphere. The storage capacity of seawater is estimated to be 5000~10,000 GtC. However, the process is slow and limited to surface seawater, so some scholars have suggested that the CO_2 ocean storage process can be accelerated and the

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

ocean's ability to absorb CO_2 can be improved by directly injecting CO_2. Therefore, this section will focus on direct injection strategies that can be applied on an industrial scale. The way to implement ocean storage of CO_2 is shown in Figure 19. Usually, CO_2 is transported to the storage site by ship or pipeline and injected into the ocean. The phase state and density of CO_2 are different with different injection depths, and the storage effect is also different. Generally, with the increase of CO_2 injection depth, the retention of CO_2 increases. Above 500 m, CO_2 is gaseous and below it is liquid. The density of CO_2 above 3000 m is less than that of seawater, and the density of CO_2 below 3000 m is greater than that of seawater. Therefore, when CO_2 is injected above 3000 m, CO_2 will rise due to positive buoyancy, causing part of CO_2 to float to the surface water before dissolution and enter the atmosphere again [259]. When CO_2 is injected below 3000 m, CO_2 should be subject to negative buoyancy and sink, so a liquid CO_2 "lake" will be formed on the seabed, thereby minimizing the risk of CO_2 leakage. Although compared with geological storage, marine storage seems to be safer. However, most CO_2 will dissolve in the surrounding seawater before reaching the seabed, and the CO_2 "lake" may also be disturbed by the ocean current. In addition, due to the influence of chemical potential, the CO_2 "lake" will also continue to dissolve, which will change the CO_2 concentration and pH value of the seabed and affect the marine ecosystem [260]. And the more concentrated the emission of CO_2, the greater its potential impact [261]. Widdicombe et al. [262] studied the impact of seabed CO_2 leakage on macrobenthic animals. The authors found that CO_2 leakage will have a significant impact on seabed animals, but the impact may disappear soon. The seabed fauna community will quickly recover to its original state, depending on the species of fauna and the characteristics of the habitat. Some scholars proposed storing CO_2 in deep-sea sediments, where CO_2 is in a liquid state and its density is higher than the overlying interstitial fluid so that the injected CO_2 remains gravitationally stable. This overcomes the problem of CO_2 escaping due to its buoyancy when geologically storing CO_2 [263].

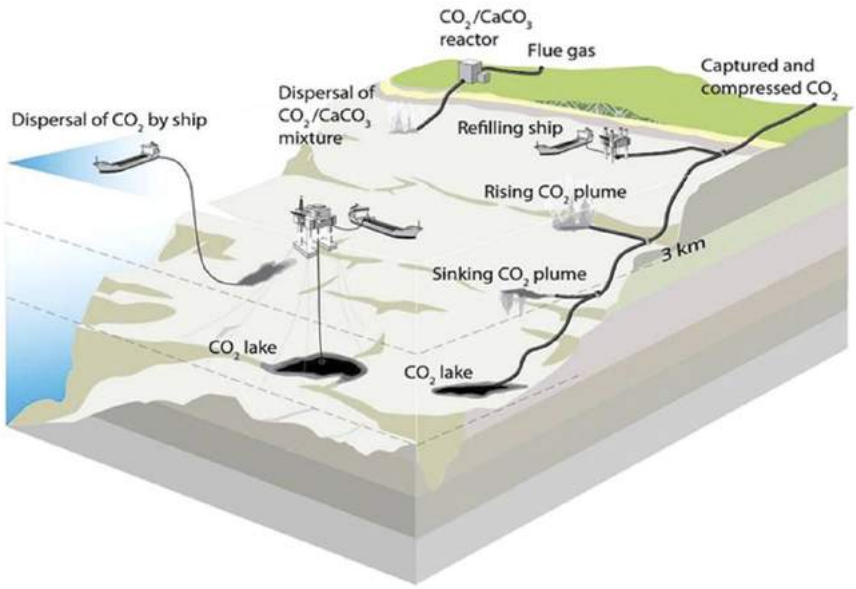

Figure 19. Strategies for ocean carbon sequestration.

Another CO_2 storage method is to store CO_2 through hydrate. Under the conditions of high pressure and low temperature in the deep sea, the interaction between CO_2 and seawater will be conducive to the formation of CO_2 hydrate. CO_2 molecules in CO_2 hydrate are locked in solid cages formed by water molecules, preventing CO_2 from dissolving into seawater. The formation and stability of CO_2 hydrate are affected by the depth and ocean thermal gradient. Figure 20 shows the phase equilibrium of CO_2 hydrate superimposed on the hydrothermal gradient of the ocean and the geothermal gradient of the seafloor. It can be seen from the figure that in seawater, CO_2 hydrate is formed and stable in the area

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

bounded by AB, while in sediment, the stable area is bounded by BC. The exact depth of these points is affected by the specific water and geological conditions at each location [260]. When CO_2 is injected into deep-sea sediments, the formation of CO_2 hydrate will reduce the effective porosity and permeability, thus blocking the flow of liquid CO_2 and acting as the second sealing cap above the injection site [2]. Li et al. [2] studied the formation mechanism of a self-sealing cap related to CO_2 hydrate and discussed the feasibility of storing CO_2 in deep-sea sediments. Through modeling, it is found that the critical time of CO_2 leakage has a strong correlation with reservoir properties and wellbore injection conditions. Qanbari et al. [264] found that the formation of CO_2 hydrate and the gravity stability of CO_2 can prevent the leakage of CO_2 in the upper part of marine sediments. If CO_2 is injected into the appropriate ocean depth and sediment depth, CO_2 can be reliably sealed in the sediment. As with geological storage, CO_2 monitoring is also required during ocean storage to prevent CO_2 leakage. Shitashima et al. [265] proposed a method for detecting and monitoring CO_2 leakage from the seabed. The steps of this method are summarized in Figure 21. The first is to detect CO_2 leaks using seafloor-based acoustic section tomographic scanning. Once a leak is detected, the pH/pCO_2 sensor and side scan sonar installed on the autonomous underwater vehicle (AUV) are used to map the leakage point. Finally, the remote underwater vehicle (ROV) or automatic elevator, or the Towing Multi Layer Monitoring System (TMLMS) are used to monitor the CO_2 diffusion behavior.

6. Outlook and Challenges

CiteSpace is a bibliometric software, which has been applied in different research fields in recent years. It can be used to analyze co-citation relationships, cooperative relationships, topic co-occurrence and future development trends. In this section, CiteSpace (V6.1) is used as the research tool and visual analysis is used to study 265 pieces of literature reviewed above. Through visual analysis, we can deeply understand the current research focus and future research direction in the field of CCUS.

6.1. Keyword Co-Occurrence and Cluster Analysis

Keywords are a high-level summary of the article and the core research content of the literature. Through the keyword co-occurrence map, we can analyze the current research hotspots and grasp the future research direction. The larger the node, the more frequently keywords appear. Therefore, it can be seen from Figure 22 that the current research focus in this field is CO_2 capture and storage. Among them, in CO_2 capture, the adsorption method is the research hotspot, while activated carbon is the research hotspot in the adsorption method. The main reason is that the price of activated carbon is low and the source is wide, which can significantly reduce the cost of carbon capture. Ionic liquids and metal–organic frameworks are also the current research hotspots, mainly because they can be functionalized by introducing functional groups and other methods to improve their CO_2 capture capacity. In CO_2 storage, the injection process has been studied more, because the risk of CO_2 leakage during the injection process is the highest. As for storage sites, the saline aquifers are the focus of current research, mainly due to their large storage potential, wide distribution and fewer restrictions. CO_2 utilization has not formed such a large node as storage and capture, because there are many CO_2 utilization routes, and there are no particularly advantageous utilization routes, all of which have more or fewer disadvantages. At present, the research focuses on the catalyst for CO_2 chemical conversion and the production of biofuels. Copper-based catalysts have attracted more attention. It is widely used in CO_2 catalytic hydrogenation to methanol. Methanol can be used to supplement or partly replace petroleum fuels, so methanol from CO_2 has broad application prospects and is of great significance to the utilization of CO_2. Using microalgae and other microorganisms to convert CO_2 into biofuels is also a research hotspot. It can also be used to replace traditional petroleum fuels, and these biofuels may be carbon negative.

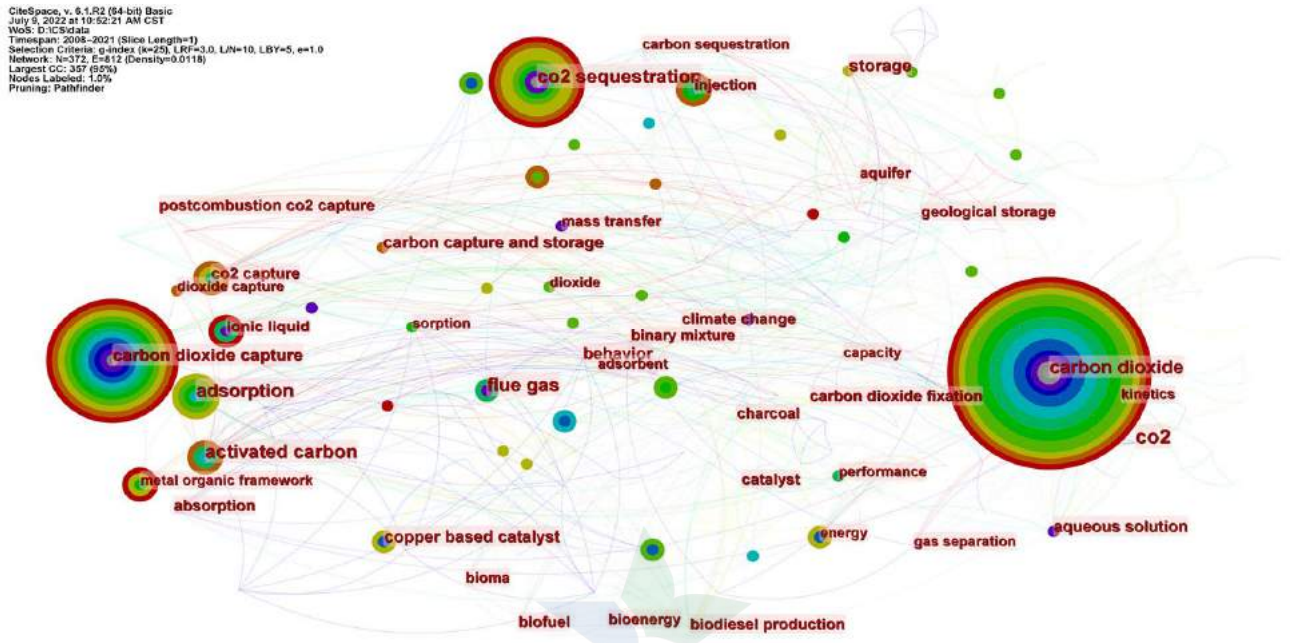

Figure 22. Keyword co-occurrence map.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Based on the keyword map, CiteSpace is used for clustering analysis, and the clustering map shown in Figure 23 is obtained. It can be seen from Figure 23 that the cluster module value Q = 0.7714 > 0.3, and the cluster average contour value S = 0.8951 > 0.5, indicating that the cluster is reasonable and the cluster structure is significant. Cluster analysis generated a total of 13 categories. Cluster 0 # is an ionic liquid, which is a new "green solvent" and is widely used in the field of gas absorption. At present, the research focus in this field is to connect ionic liquids with specific functional groups to obtain functional ionic liquids, so as to improve their CO_2 capture capacity. Of course, reducing the production price of ionic liquids is also the future research direction. Cluster 1 #, 7 #, 11 # and 14 # are all about CO_2 storage. The main reason is that CO_2 storage technology is one of the most effective technologies to achieve the goal of carbon neutralization, and it can store a large amount of CO_2. On the other hand, when CO_2 is sequestered, it can also be used for oil displacement, and coalbed methane displacement, generating additional economic benefits. Therefore, it has attracted extensive attention from all countries in the world. Cluster 2 # assessment is also related to CO_2 storage. Before CO_2 storage, the reservoir capacity needs to be evaluated to ensure that the reservoir has the capacity to store CO_2 on a large scale. It is also necessary to evaluate the integrity of the caprock to prevent CO_2 leakage through the caprock. The hydrogeological environment and geological structure of the storage area also need to be assessed to ensure long-term storage of CO_2. Cluster 9 # is a carbon credit, which is an important tool to slow down global warming. Carbon credit trading takes carbon emission allowances as a scarce resource and has commodity attributes for public trading, which is the core economic means to achieve carbon emission reduction. But the current carbon credits lack a unified standard, hindering globally coordinated action on climate issues. At the same time, in addition to the influence of market factors, policy factors are more likely to affect the carbon trading market. Therefore, it is necessary to establish a globally unified carbon emissions trading system, establish a sound carbon emissions trading market supervision system, and accelerate the construction of a mature carbon trading market. Cluster 10 # is mineral carbonization, which is similar to CO_2 flooding. It can not only effectively fix CO_2, but also may generate additional benefits. Mineralization of alkaline solid waste is the future research direction, mainly because of its low cost, and it can also play a certain role in the utilization of solid waste to achieve a win-win situation. It can also be seen from the side that CO_2 storage, which can generate economic benefits, is the focus of global scholars. Cluster 12 # is a nanoparticle. The main application of nanoparticles is the solid adsorption technology of CO_2. Porous organic polymers (POPs), metal–organic frameworks (MOFs), mesoporous materials, etc. belong to the category of nanomaterials. Nanomaterials have large chemical activity and surface energy and are easy to combine with foreign atoms to form stable structures. As an adsorbent, it has the following advantages: super adsorption capacity, Wide application range of pH, and high selectivity. Therefore, nanomaterials are the development focus of solid adsorption technology in the future.

6.2. Analysis of Cooperation Networks between Countries and Institutions

From Figure 24, it can be seen that the countries with the largest number of publications are China (77), the United States (50), Australia (43), Malaysia (19), the United Kingdom (18), India (15), Japan (15), South Korea (13), Canada (13), Iran (9) and Germany (9). In addition to Australia and Malaysia, the carbon emissions of the remaining nine countries are among the top ten in the world. This shows that these big carbon-emitting countries have all noticed the impact of greenhouse gases (especially CO_2) on the Earth's environment. At the same time, these countries have also taken action to support some institutions and scholars to study how to reduce the CO_2 content in the atmosphere. The number of papers published by China, the United States and Australia is far ahead of other countries, indicating that these three countries have more research on CCUS. As can be seen from Figure 24, China has more cooperation with Australia and the United States, while other countries have less cooperation. On the whole, there is little cooperation between countries at present, and

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

international cooperation needs to be strengthened in the future to jointly tackle global warming. It can be seen from Figure 25 that the institutions with more documents (only those with more than four documents) mainly include: Monash Univ (20), Chinese Acad Sci (13), Univ Melbourne (6), Univ Sains Malaysia (5), China Univ Petr East China (4), Carnegie Mellon Univ (4), Cranfield Univ (4), Kunming Univ Sci & Technol (4), Chongqing Univ (4), Dalian Univ Technol (4), Curtin Univ (4). These institutions are all universities, and mainly universities from Australia and China. Among them, Monash University in Australia and the Chinese Academy of Sciences in China are far ahead of other universities in terms of the number of papers issued, which shows that these two universities are at the forefront of CCUS research. Monash University has more cooperation with the Malaysian University of Science and other universities such as Carnegie Mellon University, Cranfield University and other American and European universities, while the Chinese Academy of Sciences has less cooperation with other universities. In general, the overall cooperation density is low, and all universities and institutions should actively cooperate to jointly cope with global warming.

6.3. Keyword Highlighting Analysis

It can be seen from Figure 26 that from 2012 to 2016, the mass transfer process of CO_2 is a research hotspot, and the capture and storage of CO_2 involve the mass transfer of CO_2. The research on the mass transfer process can help capture and store CO_2 better. The research hotspot from 2013 to 2014 is hydrogen production, mainly because catalytic hydrogenation of CO_2 is the most potential technology in CO_2 chemical conversion, but the source of hydrogen is a problem. Only by using renewable energy to produce clean hydrogen, can it really play a role in the utilization of CO_2. The research hotspot in 2014–2015 is simulation. Using software to simulate CO_2 transport and storage processes can help CCUS technology develop faster. The research hotspot in 2015–2017 is transformation. Through a chemical reaction, mineralization and biological utilization, CO_2 can be transformed into useful products to reduce the CO_2 content in the atmosphere. The research hotspot in 2016–2017 is water, and saline water layer has received extensive attention due to its huge storage potential. The research hotspot in 2016–2018 is a CH_4 model for making it from CO_2 that can not only reduce the CO_2 content in the atmosphere but also solve the global energy crisis, which can be said to be killing two birds with one stone. At present, the main problem is the transformation cost and efficiency. The model mainly refers to the decision-making model, which is used for the selection of CO_2 storage sites. Because the selection of a CO_2 storage site is affected by many factors, and each factor is crisscrossed, it is difficult to make the optimal choice only by subjective inference and experience. Therefore, a decision model is established to select the storage site of CO_2. In recent years, the research focus in the CCUS field is CO_2 storage and supercritical CO_2. As mentioned earlier, CO_2 storage is an indispensable part of achieving the goal of carbon neutrality. Supercritical CO_2 has both gaseous and liquid properties, which makes it widely used. Therefore, it is also the current research hotspot.

6.4. Challenge

Based on the above overview of CCUS technology, the current challenges faced by CCUS technology are as follows:

(1) Technology

At present, CCUS technology has some disadvantages, such as high energy consumption of traditional chemical absorption technology, evaporation and oxidative degradation

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

of absorbent, which increase the operation cost. The CO_2 selectivity of physical absorption technology is weak. New capture technologies such as ionic liquids are expensive and complicated to manufacture. The process of solid adsorption technology is complicated, and it is difficult for a single set of equipment to ensure the long-term operation of the process, with high investment. Low-temperature separation technology has high energy consumption, and microalgae, chemical chain combustion and electrochemical technology are difficult to achieve long-term stable operation. At the same time, the flue gas contains a lot of impurities, which will affect the efficiency of CO_2 capture. These impurities will also affect CO_2 pipeline transportation and threaten the integrity of the pipeline. At present, there is little research in this area, which needs further in-depth study. In CO_2-enhanced energy production, the miscibility of CO_2 and CH_4 will reduce the recovery of CH_4 and increase the exploitation cost. CO_2 will also affect the surface structure of shale and coal, resulting in a decrease in CO_2 adsorption capacity and permeability. In the chemical conversion process of CO_2, due to the thermodynamic stability and kinetic inertia of CO_2, the conversion process is very difficult. Although many CO_2 conversion routes have been developed, most of them only consider the possibility of reaction and do not consider economic factors. The main problem of CO_2 catalytic hydrogenation is cheap and clean H_2. Photocatalysis and electrocatalysis are currently facing challenges such as low productivity, difficult product separation and poor catalyst stability. In CO_2 storage, the main problem is CO_2 leakage. Whether in the injection process or long-term storage process, CO_2 leakage is the first problem to be considered. The unpredictable leakage risk restricts the development of CO_2 storage technology. To sum up, we should strengthen the research and development of CCUS technology, improve the feasibility of the technology, and realize large-scale commercial promotion and application as soon as possible.

Figure 26. Keyword highlighting.

(2) Economy

Economic problems are an important factor restricting the development of CCUS technology. The capture, transportation, utilization and storage of CO_2 are faced with high costs. Except for large CO_2_EOR projects, other CCUS projects have difficulty achieving profitability. Long-term high-cost investment and low-profit returns make investors lack investment motivation, which restricts the commercialization of CCUS. Countries should establish special funds for CCUS, introduce economic incentives and preferential tax policies, and help enterprises reduce CCUS operating costs. Without government support, current CCUS projects find it difficult to achieve profitability, which seriously affects the enthusiasm of enterprises to carry out CCUS demonstration projects.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

(3) Policy

At present, most countries in the world have not issued policies, laws, regulations, technical specifications and standard systems on CCUS. They are important links in the industrialization development of CCUS, which also restricts the development of CCUS technology. At the same time, the policies that have been issued are not targeted, and CCUS needs more specific support policies. Therefore, countries all over the world should improve and optimize the CCUS legal and regulatory system as soon as possible, formulate a scientific and reasonable standard system for the construction, operation, supervision and termination of CCUS projects, and standardize CCUS activities. There should be a multi-industry cooperation mechanism to promote the development of the whole industry chain of CCUS. Establish a carbon emission trading market, incorporate CCUS into the carbon emission trading system, accelerate the establishment of carbon emission reduction methodology for CCUS projects, and provide a theoretical basis for calculating the CO_2 emission reduction of CCUS projects. In addition, with the energy crisis caused by the conflict between Russia and Ukraine, many countries have weakened the implementation of the carbon neutral target, or even abandoned the carbon neutral target, which also restricts the development of CCUS technology. Governments should deliver on their commitment to CCUS and play a key role in facilitating its deployment. At the same time, an international unified regulatory framework should be established to encourage the private sector to actively participate in and invest in CCUS projects, which will accelerate the commercialization of CCUS technology. In the future, CO_2 may become a resource needed by various economic sectors, which will help to achieve climate goals.

The development of CCUS technology will not only face the above challenges, but it may also bring environmental problems. For example, leakage risks are prone to occur during CO_2 transportation and storage, which will pollute the soil and damage local water quality, and even cause harm to local people. At the same time, this will affect the public acceptance of CCUS technology and hinder its development.

7. Conclusions

In order to achieve the goal of CO_2 emission reduction, CCUS technology has become a research hotspot. This paper summarizes various technologies and problems related to CCUS, and draws the following conclusions:

(1) With the emergence of new solvents such as solvent mixed absorption technology and ionic liquid absorption technology, solvent absorption technology will still be the first choice for large-scale CO_2 capture in the future. Solid adsorption technology is currently a research hotspot, especially metal–organic frameworks, whose functional characteristics make them have great development potential for the future. The development of mixed-matrix membranes, gas-absorbing membranes, and facilitative membranes has improved the permeability and selectivity of membrane separation technologies. Low-temperature separation technology, microalgae, electrochemical looping combustion technology and electrochemical technology have made some important progress in recent years, but there is still a long way to go before large-scale commercial use.

(2) Pipeline transportation is the most economical way to transport large amounts of CO_2. For long-distance pipeline transportation, dense phase transportation and supercritical transportation are more economical. In the pipeline design process, the temperature and pressure changes along the line should be considered to prevent phase changes. At the same time, it is also important to consider the impact of impurities in CO_2 on pipeline operation, which will not only affect the phase characteristics and physical parameters of CO_2 but also threaten the integrity of the pipeline. At present, the relevant knowledge system of CO_2 pipeline transportation is not perfect and needs further research.

(3) In enhanced energy production technologies, studying the adsorption behavior of CO_2 is the key to enhancing recovery and increasing storage capacity. At the same time, attention should be paid to the influence of CO_2 on the reservoir to prevent the reduction of the permeability of the reservoir. In the chemical conversion of CO_2, catalytic hydrogenation

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

of CO_2 is the most promising technology, but cheap and clean H_2 is currently the main problem. Coupling electrocatalytic technology with renewable energy is an important development direction for the future. Catalysts are required for almost all CO_2 chemical conversions, and catalyst activity and selectivity can be enhanced by doping and alloying with foreign atoms. CO_2 mineralization requires a large amount of energy, and the energy in the exothermic reaction should be recovered to make the mineralization economical.

(4) In CO_2 storage, geological storage is currently the main method. The selection of a storage site is the first step of geological storage, but there are few studies on this aspect at present. The storage mechanism is the theoretical basis of geological storage and determines the efficiency of geological storage. Preventing CO_2 leakage is an issue that must be considered in geological storage, and CO_2 leakage may pollute groundwater. At the same time, the impact of geochemical reactions on the caprock cannot be ignored. At present, the monitoring technology of CO_2 storage is relatively mature and has been applied in different projects. In ocean storage, the CO_2 injection depth is different, and the storage effect is also different. Due to factors such as storage costs and the international law of the sea, ocean storage has not yet entered the stage of practical application.

Finally, the research status, research hotspots and cooperation networks of CCUS are summarized using CiteSpace software. To sum up, CCUS technology is developing rapidly, which is a favorable choice to deal with climate change. Although CCUS technology currently faces some technical challenges, high cost is the key factor hindering the development of CCUS technology, which limits the large-scale deployment of CCUS technology. Government fiscal policy is a key means to promote the development of CCUS technology. The government should promote the rapid development of related industries through direct investment. At the same time, in order to improve public awareness of the environmental impact, public education and publicity on CCUS technology should be strengthened.

Abstract: Technology advancements have enabled the capture of Renewable Energy Sources (RES) on a massive scale. Smart Grids (SGs) that combine conventional and RES are predicted as a sustainable method of power generation. Moreover, environmental conditions impact all RES, causing changes in the amount of electricity produced by these sources. Furthermore, availability is dependent on daily or annual cycles. Although smart meters allow real-time demand prediction, precise models that predict the electricity produced by RES are also required. Prediction Models (PMs) accurately guarantee grid stability, efficient scheduling, and energy management. For example, the SG must be smoothly transformed into the conventional energy source for that time and guarantee that the electricity generated meets the predicted demand if the model predicts a period of Renewable Energy (RE) loss. The literature also suggests scheduling methods for demand-supply matching and different learning-based PMs for sources of RE using open data sources. This paper developed a model that accurately replicates a microgrid, predicts demand and supply, seamlessly schedules power delivery to meet demand, and gives actionable insights into the SG system's operation. Furthermore, this work develops the Demand Response Program (DRP) using improved incentive-based payment as cost suggestion packages. The test results are valued in different cases for optimizing operating costs through the multi-objective ant colony optimization algorithm (MOACO) with and without the input of the DRP.

1. Introduction

Because of increased awareness of Energy Consumption (EC) and production worldwide, the market share of renewable sources has been increasing. Renewable Energy Sources (RES) are predicted to outperform fossil fuels in monthly power generation. There is a departure from the industry's restraint and unsustainable resources, and consumers and energy providers have developed using 23% green power. However, the infrastructure operations are complicated, and utility companies and consumers are challenged due to the

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

inconsistency of market demand and supply of extensive energy that RES and utility companies and consumers can meet. The energy company applied Smart Grid (SG) technology to stabilise the Green Energy Supply (GES) and make RE trustworthy and future-proof.

A traditional Distribution System (DS) supports the energy flow from suppliers to users. Energy transmission and distribution with SGs are performed using a SG as a one-way electrical interconnection system integrated with massive production points as the only energy source at multiple locations. The industries require multiple extra production points combined with the increased volume of smaller RE generation plants. The new paradigm could not be continued by the conventional method, which depends on the operator-enabled power system, and highly flexible operation management is allowed because a SG solution replaces it.

Future SG-based DSs will also be able to meet the increased use of renewable Wave Swell Energy (WSE) sources that behave in a standard method that repeats itself. The operation's security may be endangered due to this [1]. There is a need for Advanced Measuring Infrastructure (AMI) [2] to guarantee the cost-efficient and secure operation of these systems and to use cutting-edge design for Distributed Energy Resources (DER) [3,4]. AMI provides smart meters, which have the features of remote control, monitoring, and readability, by creating bidirectional telecommunication between electricity companies and customers, embracing data collection and transmission by energy providers, information analysis and processing, and implementing EC management to ensure system reliability and balance supply and demand [5,6]. Since the environmental impact is reduced, the market situation, reliability, and service should be enhanced. An SG will incorporate information and Communications Technology (ICT) into each component, such as electricity generation, EC, and delivery. An SG makes the seamless integration of unreliable RES and the potential for efficient power distribution and delivery highly possible. The scale of SG adoption is the basis for efficiently incorporating RE into the energy sector, supporting technologies such as smart meters and the Internet of Things (IoT), and big data will drive it forward. While deploying RE systems, control is a complex aspect. For super-performance and reliable operations, WSE is required. By implementing digitally enabled SGs, such as the IoT, consumers and energy suppliers will be provided with advanced tools for monitoring and regulating SG performance. It is performed by controlling multiple devices at production points and households.

Vast IoT infrastructures are supported by adopting SG devices and facilitating leveraging skills for digital risk protection. There is more adaptability of the network to oversupplies or electricity shortages that the RES has in common with a conventional model integrated with grid-connected devices. The resource computer and the smart devices are connected, and the essential information is collected to cope with electricity usage and help stabilize the whole grid. Utility companies advance their operations by carefully analysing the data collected in the SG network. Data associated with operational device status, quality of power, self-test, smart meter, and consumption level are collected by advanced metering infrastructure.

Few data are considered for real-time processing due to edge computing and 5G adoption. Profound knowledge of performance skills, enhanced performance, and consumer behaviour is enhanced using big data. Energy providers enhance SG optimization and more customer engagement, along with data analytics. RES especially encourages the application of big data and predictive analytics. Because of it is unpredictability, sustainable electricity demands reasonable efforts due to its instability to incorporate it into the energy network based on homogeneous fuel. The suppliers can project energy generation and EC rates, mitigate risks, and make constructive decisions based on the processed data.

With the help of big data analytics, utility companies can improve the efficiency of SG based on how they use real-time data or how well they collected data in the past—continuous monitoring systems and improved energy production and distribution work to address the current challenges simultaneously. For the SG, it is predicted that the latest hike in variable wind and generation of SP will boost more Renewable Energy (RE)

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

shares in the future in the cumulative generation portfolio, and challenges related to SG management make the task of predicting WP essential for the SG. The relevant balancing actions are getting more complicated, leading to greater variable WSE penetration.

The existing applicable methods' inventory, including data from the meteorological department and power system, and disseminating this data, which requires the communication structure, are essential. The obtaining of accurate information that requires PMs, such as software and data, and the need for infrastructure to generate and communicate this information are included in the proposed model.

The unsureness in the behaviour of WSE is one of the significant demerits in RES management. Network operators always use energy storage local services to control manufacture shortages and balance EC and production before using WSE and the rest of the REs in the power system. Now, storage and finding a solution for solving this unsureness are more mandatory than ever with the emergence of WSE and the absence of certainty in production capabilities. Demand Response Program (DRP) usage is one of these solutions [7].

Recently, by conducting studies to implement better Demand-Side Management Programs (DSMP) and roles, a balance has been formed between EC and RE generation. A WSR-based SG is managed using a DRP [8]. To ignore the use of the pollution emission function to model the micro-grid management, the resolution for the proposed model is made through the Particle Swam Optimization (PSO) algorithm. To mitigate the cost of functioning and emissions, in [9], the evaluation of multi-objective operation planning in a SG distribution with WSR was performed as a probabilistic model; in Wind Power (WP) and Solar Power (SP), the variations are modelled with the help of Probability Density Functions (PDFs). This reference does not consider the corresponding generation of SP and WP modelling. On the other hand, there is an omission from the pollution function's definition for elements such as Sulphur Dioxide (SO2) or Nitrogen Oxides (NOx) and for problem-solving the three-constraint method is used. Reference [10] discussed the same type of issue, which was solved using the scenario tree method; the researchers in this study ignored the SP modelling.

In the Mesh Adaptive Direct Search Method (MSDSM), the generation of RE that causes uncertainty was ignored [11]. A single objective function changes a multi-objective function, and a method called Mixed Integer Programming (MILP) is used to resolve the recommended method. To increase social welfare, [12] studied the DSMP in an SG's application, assuming the generation of WP, i.e., a WPP and the improbability it caused. The authors do not consider the benefits of SP generation, and the incentive-based DRP, which motivates customers to participate, is not used in this research. In [13], the Monte-Carlo-Method-Based Stochastic Planning Approach (MCMBSPA) was suggested to model the wind and Demand Response (DR) stochastic behaviour in an energy market after considering the WP's impact as operational storage.

To develop the DRP, the authors of [14] used incentive-based payments as cost-suggested packages. The simulation results are reviewed in three separate instances to optimize operating costs and productions with and without DR. Users in an SG-connected microgrid with energy storage used an independent and distributive DSMP based on Bayesian Game Theory (BGT) designed by [15]. Each user's EC of shiftable loads is modelled as a noncooperative III-players game with partial data in which all users compete compared with the storage element and all other microgrid users.

A new method [16] has been developed for reducing residual demand to improve the mix and spatial distribution of WP and PV capacity in Europe. Micro-Grid Energy Management (MGEM) is described as mixed-integer linear programming [17] and presents a new multi-objective solution and DRP. DR is included in the optimization challenge to prove its impact on energy dispatch and their technological and commercial benefits.

A stochastic optimization framework for DR with dynamic pricing and Plug-in Electric Vehicles (PEVs) is by [18]. This paper proposes a stochastic optimization framework for demand response that considers dynamic pricing and PEVs. The limitations of this work

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

are that it does not consider uncertainties in the energy stock market and the PEV charging behaviour. The proposed model in [19] is a dynamic Zonal Congestion Management (ZCM) model based on the DRP. The model uses power tracing techniques and sensitivity analysis to determine the congestion control zones based on an introduced Congestion Index (CI) that considers both the effectiveness of congestion alleviation and the responsibility for congestion creation. The proposed model does not consider integrating RE sources, which can impact congestion management in the long run as the distribution of RE in the energy mix increases.

Further, the model assumes that the system operator has perfect information about the power system, which may not always be true in practice. Inaccurate information can lead to ineffective congestion management.

An "Integrated Energy Management System (EMS) for Microgrids of building prosumers" was proposed by [20]. A microgrid EMS for building prosumers is the proposed design. It reduces microgrid operation costs for buildings, RES, ESS, and PEVs. However, the proposed EMS does not consider uncertainties in the energy market, such as fluctuating energy costs and unpredictable weather patterns that affect RE generation. Although the proposed optimization problem is designed to minimize a microgrids' operation cost, it is unclear whether it can be scaled to larger microgrids or distribution networks. An optimal EMS for microgrids considering ESS, DR, and RE generation was proposed by [21]. The paper proposes a scenario-based EMS model for microgrids (MGs) in stand-alone mode that utilizes ESSs and demand-side flexibility to ensure autonomous power supply while maintaining stability. The potential limitation of this study is that it assumes perfect information, which may not be realistic in real-world scenarios. The study focuses on reducing network energy losses but does not consider other principal factors, such as environmental impacts or economic feasibility.

This paper optimizes the smart grid's WP, SP prediction, and DRP to minimize energy costs and emissions. WP and SP prediction were tested using cutting-edge Deep Learning (DL) models. Further, the proposed DRP is implemented to base the DRP method on an incentive, as the participation of consumers in these programs is deemed voluntary. To provide DR packages, such as cost and storage, for commercial, industrial, and residential consumers based on their situations, consumers select one of the presented packages and contribute to a DRP. The Water Surface Pressure Gradient (WSPG) is modelled using Rayleigh and the beta Probability Density Function (PDF) proposed in this paper. Considering the fuzzy-mechanism-based Pareto criterion in integration with nonlinear sorting, the Multi-Objective Ant Colony Optimization (MOACO) method is used to optimize the DRP.

The paper is structured as follows: Section 2 presents the predictions of SP and WP generation, Section 3 presents the MOACO-based DRP model, Section 4 presents the result and discussion, and Section 5 concludes the work.

2. RES Prediction

2.1. Solar Power Prediction (SPP)

The model is initialized by integrating Numerical Weather Predictions (NWP) to start with an ideal stage. Weather satellites and ground weather stations provide these weather predictions. Because of huge-scale forces, the predicted weather modifications, such as SP, speed, and clouds, can be assessed using standard operational NWP models at national centres. However, the prediction of WP or SP resources, adapted to the WP or SP plant's particular application and the WP or SP plant's location, is permitted by personalized NWP. A chance to assimilate exclusive local observations at the neighbouring power plant is provided. NWP models vary in the model grid's resolution and spatial model domain. The model grid's conventional spatial resolutions of 50 km for the global and approximately 2 km for the region are integrated with the global PM, i.e., globally and regionally, with an area-restricted MESO scale to operate. Well-designed global PMs forecast large-scale synoptic weather patterns. However, with less than 10 km of horizontal resolution, the regional models' current role is overtaken by the persistent hike in computer power.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

NWP approaches have been introduced based on the application and related time scale. The short-term time scale, from minutes up to a few hours, has adequate time series models that use on-site measurements. The ground-based sky imagers are used to acquire high spatial and temporal resolution that enables intra-hour prediction. Cloud motion vectors from satellite-image-based forecasts show a reliable performance for the next 30 min to the next 6 h. Photovoltaic (PV)-SG requires a prediction of up to 2 days. The NWP models are the basis of this prediction.

This section provides the basic ideas and information needed to understand and make solar power predictions. Primary factors such as SP monitoring, performance assessment metrics, and solar PMs that need general inputs are used to measure the performance of predictions.

2.1.1. Components and Applications of Irradiance

With a difference of less than 0.1% per year [22], there is 1.36 kWm^2 of extraterrestrial SP at the top of the atmosphere. How good a variable value depends on the local weather and where it is in ground-level SP. Global Horizontal Irradiance (GHI) is the absolute solar power that hits a horizontal ground surface. The GHI's are classified as Diffuse Irradiance and Direct Normal Irradiance (DNI), where the energy from the ground level usually comes from the solar beam and contains a small volume of circumsolar energy [23]. Diffuse Horizontal Irradiance (DFI) energy propagates through the atmosphere. Equation (1)

$$\mathrm{HI} = \mathrm{DNIcos}(\theta_z) + \mathrm{DIF} \quad (1)$$

The association between DNI, GHI, and DFI is where the solar zenith angle is θ_z and the solar elevation angle $\theta_e(\theta_z + \theta_e) = 90^\circ$ is the balancing angle. DNI develops more sensitivity towards atmospheric cloud covers and aerosol concentrations when compared with GHI. For example, the DNI is dropped by moving clouds in a few seconds from hundreds of W m^2 to 0 [24].

There is a considerable correlation between operational PV generation and GH. As a result, the increasing development of PV capacity has motivated future research on GHI resourcing and prediction. Alternatively, the real-time tracking of the SP results only in using DNI components by the Concentrated Solar Power (CSP) technologies. Thus, a powerful desire for researching and predicting DNI resourcing is stimulated by the latest increase in the development of global CSP systems.

The future power result, or SP, is the result of the solar PMs. This is the difference in the value of the PMs between models and choosing the values needed to make a PM. The following are the inputs commonly used in intra-hour solar prediction applications: local weather data, sky image features, and historical and current energy data.

2.1.2. Measured Irradiance Data

Solar PMs' endogenous inputs and training targets represent clear-sky indices and irradiance measurements. The literature uses temporal resolutions of 1 to 5 min combined with lagged 30 to 60 min data for intra-hour forecast horizons. However, this is not enough for the solar ramps' accurate prediction (caused by evolving clouds) to be performed by solar PM containing just endogenous inputs [25]. To the PM, there is a necessity for exogenous inputs to be predicted since they are important for plant management, operations of rapid distribution, and enabling inverter control by the solar ramp [26]. The accuracy that SP expects in predicting solar ramp measures is enhanced by exogenous inputs such as cloud cover information and weather data provided by sky images [27].

2.1.3. Meteorological Data

Table 1 contains the meteorological variables commonly used for deploying the intra-hour solar prediction. The meteorological data are received from the weather stations of neighbouring or local NWPs. In situ observations are chosen because they have a high temporal resolution. In the absence of in situ observations, high-resolution time series

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

of NWP data from NWP are interpolated as global inputs [28]. Data normalization, a commonly used and effective method, improves the sturdiness and standardisation of data-driven models [29]. Data are normalized by increasing the certainty of NWP data, improving data stability, and simplifying object-to-data mapping. The Min–Max scaling score normalization method is frequently used to normalize the meteorological data in the solar prediction domain. The definition of Min–Max feature scaling normalization is as follows: Equation (2):

$$X_{\text{normalized}} = \frac{X - X_{\text{min}}}{X_{\text{max}} - X_{\text{min}}} \quad (2)$$

where a weather variable's value is X, set the data at the MIN and MAX as X_{min}, X_{max}. The definition of the standard value of normalization is as follows: Equation (3)

$$X_{\text{normalized}} = \frac{X - \mu}{\sigma}, \quad (3)$$

where X's mean and standard deviations are 'm' and 's'.

Table 1. Input variables for prediction applications.

Class	Variables
SP	GHI, DNI, DIF, open-sky indices, spectrum energy, and neighbour energy.
Weather Data	Conditions such as pressure, temperature, humidity, Wind Speed (WS), wind direction, rainfall, aerosol optical depth, and cloud cover
Features of Sky Images	Cloud movement vector, cloud cover ratio, image features.
Other	Solar zenith, azimuth, local time, solar time

2.1.4. Local Sky Imaging Data

The use of cloud indices provided by NWPs every 6 to 12 h is permitted for intra-day and day-ahead solar prediction. However, to be used for intra-hour solar prediction, this is not sufficient [30]. So, sky imagers—the local sensing systems—provide information related to ground-detected clouds in integration with greater temporal and spatial resolution. Relevant studies obtain summarized statical features from sky images as exogenous inputs because millions of pixels are checked in a high-resolution sky image. Feature Extraction (FE) is performed using statistical RGB analysis or cloud detection methods. A complete sky image (FE) is presented in [31]. However, these image-based FE methods that minimise installation and transfer costs are usually performed manually.

2.1.5. Mathematical Modelling

The prediction problem is as follows: a time of historical climate data is given $\{x_1; x_2 \ldots x_n\}$ and the number of weather inputs is represented by "n". The following is a mapping function "f" between future solar PV and historical weather data defined to forecast day-ahead solar PV by Equation (4).

$$\hat{y} = f(x_1, x_2 \ldots, x_n) \quad (4)$$

The solar PV-PM with n = 6 weather inputs' is shown in Figure 1.

As PV panels become more affordable, utilities are increasingly installing high potentials at Solar Power Plants (SPPs); later, the output power is regulated via an inverter to satisfy the guidelines of maximum capacity, commonly referred to as curtailment. However, especially during the winter, the day's maximum power output mismatches with the sun's position due to curtailment. As a result, in our work, the target values do not match the precise amount of energy generated by PV panels, which are more closely related to the sun's location throughout the year. However, the target values include the power outputs

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

of a regulated SPP that fails to track the sun's position very precisely. This work assessed the optimal power generation curve daily for the inverter effect. We defined "ideally" as the volume of SPP electricity output generated in exceptionally sunny weather with no cloud cover but with curtailment.

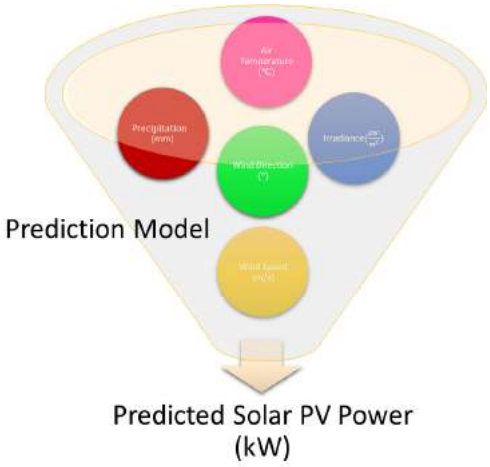

Figure 1. Solar PV-PM.

Due to the extensive data, the true daily pattern is difficult to observe. On the other hand, the greatest values of the blue "lines" represent the highest daily power generation, which varies seasonally and monthly. Additionally, the red cosine of the sun's zenith angle showed that maximum power outages would not occur daily. The monthly optimum condition of the day is defined in this work, i.e., the output of the optimum day's power was determined for each month based on a historical day's sample, wherein a set of circumstances contained the energy output.

SPP per day and hour can be the value of the daily sum and the monthly maximum sum $s^{d,m} = \sum_h P_h^{(d,m)}$. A similar quantity for daily_max $S^m = Max^{(s^{d,m})}$ and monthly daily_max is computed as: $m^{d,m} = Max(P_h^{(d,m)}$ and $M^m = Max\left(m^{d,m}\right)$.

Algorithm 1 depicts the algorithm for selecting ideal days from historical data. To summarize, optimal days would have a daily sum and high output of more than enough compared with all previous days in that month. In addition, the optimum day will possess a smooth bell curve with no abrupt decrease in power production. Figure 2 depicts an ideal and a non-ideal day.

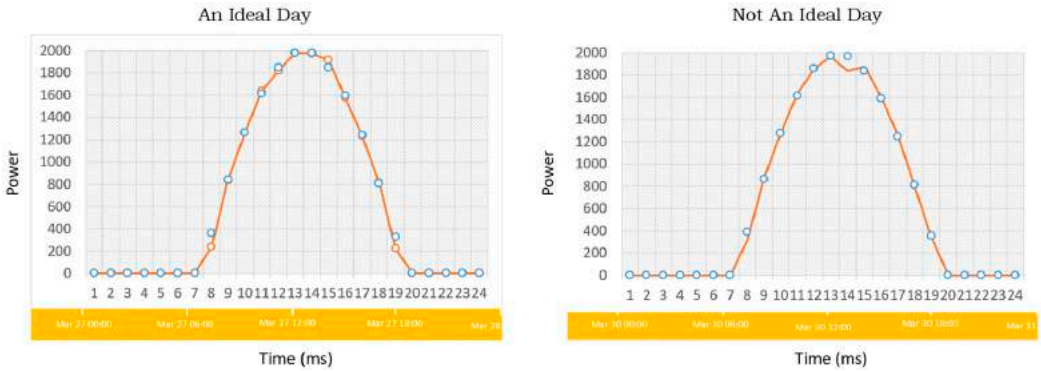

Figure 2. Illustration of an optimum day chosen on the left and a non-ideal day on the right (with a minor decrease at noon).

Step 20:	Ideal:= True;
Step 21:	End If;
Step 22:	End Do;
Step 23:	End If;
Step 24:	End Do;
Step 24:	End Do;
Step 25:	End

This work computes the "distance" or "similarity" between the actual and ideal power outputs. To summarize the method, for every training day, similarity metrics are determined. Next, the cumulative summary statistics of such a day's weather are used for training a Support Vector Regression (SVR) model, which tends to forecast the similarity metrics at the time of forecast. The hourly SP output is then predicted using the predictable similarity metrics and hourly weather data.

2.1.6. Deep Learning Models

The weather condition's temporal evolution is distributed, and its impact on SP output is investigated using the Temporal Convolutional Network (TCN)-based DL method proposed in this study. Each day has a set time, ranging from 5 a.m. to 8 p.m. for 16 h. On an hourly basis, the target SP output is measured, so each day contains 16 target values. Several methods exist for extending the network's connectivity in the time dimension, which investigates the weather data's spatiotemporal dimensions daily.

On the temporal dimension, connectivity is accomplished in phases. Figure 2 shows three temporal connection patterns evaluated: a single hour, a daily, and a hybrid model. With a weather-grid-data-based 4D tensor, the single-hour model solely considers inter-hour

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

temporal connectedness. The daily model with NWP data assumes a 4D tensor containing NWP data for the previous 16 h and an output equivalent to 16 hourly solar outputs.

- Single-Hour Model

The winning models and the tested networks are like the winning models in the ImageNet challenge: AlexNet and ResNet. This model deployed the TCN combined with the Volumetric Convolution Neural Network (VCNN) layer instead of the spatial convolution layer. On a multi-dimensional input tensor built with different weather inputs, a 4D convolution is applied by a volumetric convolution layer followed by TCN. The spatial dimensions in spatial convolution are where convolutions are exclusively applied. A 3D filter is convoluted to perform convolutions from the spatial and temporal dimensions in 4D-CNNs to extract spatial–temporal relation information automatically. The VCNN and TCN-based Neural Networks (NN) are depicted in Figure 3a–c. Throughout the temporal and spatial dimensions, the derived features are accessible to heterogeneous channels containing information about the weather using VCNN. As a result, it can recognise cloud movement patterns, which influence SP outputs.

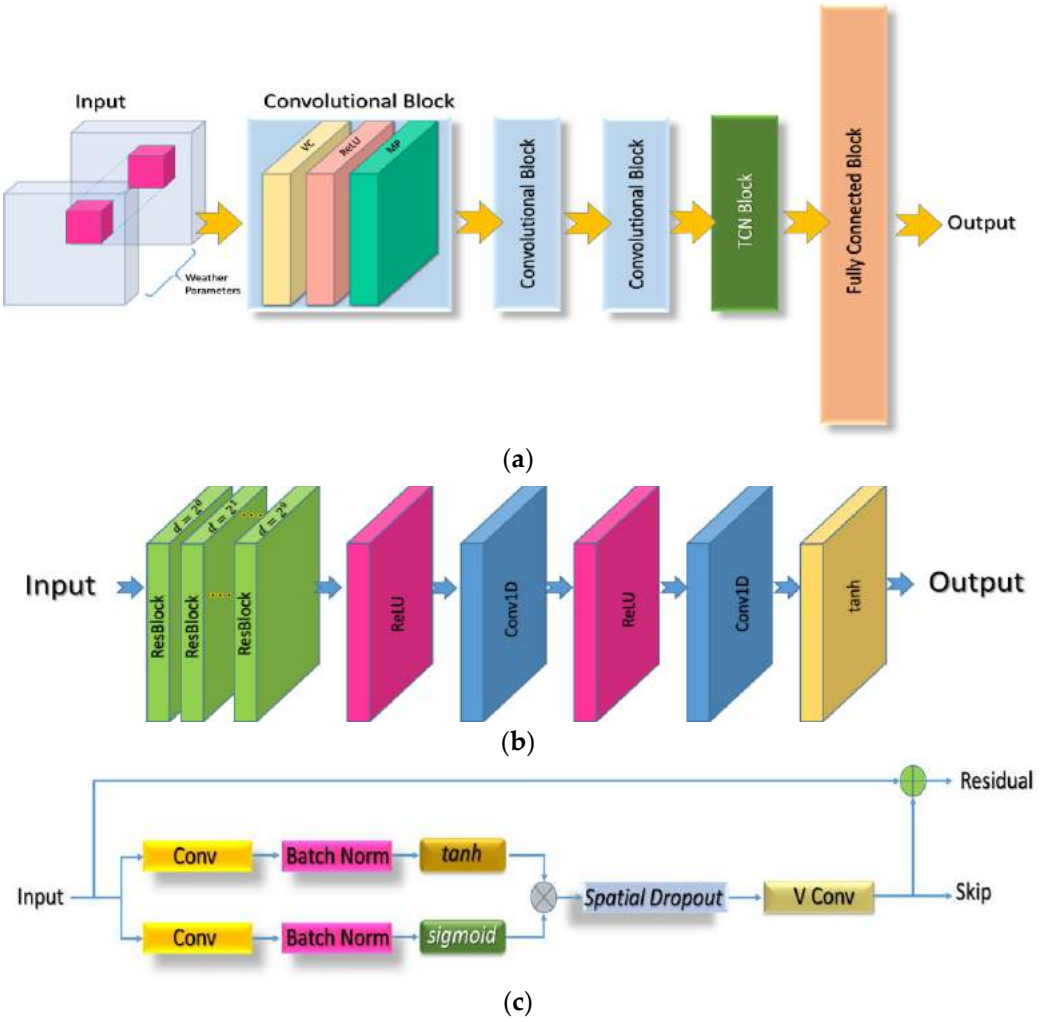

Figure 3. (**a**) VCNN and TCN-based Neural Network. (**b**) TCN Block Architecture. (**c**) ResBlock Architecture.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

The formal name for a unit's value at location (t, x, y) is inside the feature map (i, j) with a layer v_{ij}^{txy}, Equation (5).

$$v_{ij}^{txy} = \text{ReLU}\left(b_{ij} + \sum_m \sum_{r=0}^{R_i-1} \sum_{p=0}^{P_i-1} \sum_{q=0}^{Q_i-1} w_{ijm}^{rpq} v_{(i-1)m}^{(t+r)(x+p)(y=q)}\right) \quad (5)$$

where the Rectified Linear Unit is ReLU, which allows only definite outputs to be transmitted over the network, the bias of this feature map is b_{ij}, over the features from the *(i-1)* layer, 'm' indexes for the feature, the weight for value at the filter's point r, p, q is W_{ijm}^{rpq}, the time, height, and filter size are R, P, Q. With more massive convolution strides, the output layer is generally smaller, Equations (6)–(8).

$$R_{i+1} = \lfloor (R + 2 \times padT - R_i)/dT + 1 \rfloor \quad (6)$$

$$P_{i+1} = \lfloor (P + 2 \times padX - P_i)/dX + 1 \rfloor \quad (7)$$

$$Q_{i+1} = \lfloor (Q + 2 \times padY - Q_i)/dY + 1 \rfloor \quad (8)$$

(1) *Model Shorthand Notation:* A shorthand notation is used were

- A volumetric convolutional layer with spatially sized $R \times P \times Q$ filters as $VC(l, R, P, Q; dr, dp, dq)$, implied by stride $VC\ (dr, dp, dq)$;
- As implied by stride $VC(dr, dp, dq)$, a volumetric max pooling with spatial size $R \times P \times Q$ is specified $MP(R, P, Q; dr, dp, dq)$;
- The temporal convolutional layer has 'n' output nodes and is $TC(n)$;
- $FC(n)$ denotes the fully connected layers of 'n' output nodes.

(2) *Single-Hour Network Model:* Through the shorthand notation, the whole framework for the network-constructed single-hour model is Equation (9).

$$\begin{gathered} VC(128,2,11,11;1,4,4) \to MP(1,3,3;1,2,2) \to VC(384,2,5,5;1,1,1) \to MP(1,3,3;1,2,2) \to \\ VC(768,2,3,3;1,1,1) \to VC(576,1,3,3;1,1,1) \to VC(576,1,3,3;1,1,1) \to MP(1,3,3;1,2,2) \to TC(1000) \to FC(1). \end{gathered} \quad (9)$$

It is of value noting that a ReLU layer follows each volumetric convolution layer. The layer output of the last FC layer contains merely a number because our objective is a regression problem.

- TCN

The proposed TCN block model is depicted in Figure 3b. TCNs often use fundamental convolutions in which the current and previous factors determine the output at a time "t". Zero paddings are used to achieve this. To replicate the future knowledge utilization by bidirectional RNNs, this work generates the convolutions inside the TCN block in a non-casual way. In this method, apply $d = \{2^0, 2^1, \ldots, 2^9\}$ dilation rates integrated with 10 residual blocks (ResBlocks). The ResBlock uses 256 filters of size 3 and a dilation rate of d incorporated 1-D dilated convolutions, as shown in Figure 2c. Unlike the ResBlock algorithm presented in [32], batch normalization is used after dilation convolutions. If necessary, the *tanh* and sigmoid activations embrace the normalized activations. Before the last convolutional layer, which has 256 filters of size 1, a spatial dropout with a 0.5 dropout rate is used. The output activations would be an end connection, and the original input is to generate the residual connection. The sum of all skip connections is given a ReLU activation. Ultimately, two convolution layers, each possessing a 128-sized filter, are fed with the output activations. When using TCNs, a more extensive set of variables and Multiply-and-Accumulate (MAC) operations are frequently required. However, then, the well-developed hardware accelerators have made it possible to realize such systems while lowering energy costs and the requirement of silicon area and memory space [33]. Because of the Convolutional Neural Network (CNN) accelerator's structure, the accelerators try to accept three types of data reuse.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

(i) By design, the convolutional reuse allows using the same filter map activations and filter weights across the panel.
(ii) The activation of the input feature map is used again because the same input feature map is hard to understand with different filters.
(iii) The same filter weights are used on all input feature maps during batch processing.

Accelerating RNNs confronts two major tasks: For starters, because of its recurrent nature, including serial processing, it cannot exploit parallels '*m*' properly. The second issue is that computations are data dependent. As a result, a customized accelerator is created that is tuned to the computation model.

2.2. Wind Power Forecasting (WPF)

When creating a PM, spatial scales are considered. Grid balancing requirements, on the other hand, must consider the availability of WP from all Wind Power Plants (WPPs), including utilities within their service region. Mutual information, as the name implies, denotes data distributed through two variables. The degree of improbability of all other variables to be assessed and predicted is called data entropy, which measures such a degree of dimensionless statistics when one of these variables remains less.

NWP factors f_i with WP as P have mutual information as I, as Equations (10) and (11)

$$I(f_i, P) = \sum_{t,t' \in T} p\left(f_i = f_i(t), P = P\left(t'\right)\right) \log \frac{p(f_i = f_i(t), P = P(t'))}{p(f_i = f_i(t))p(P = P(t'))} \quad (10)$$

$$I\left(f_i, f_j\right) = \sum_{t,t' \in T} p\left(f_i = f_i(t), f_j = f_j\left(t'\right)\right) \log \frac{p\left(f_i = f_i(t), f_j = f_j(t')\right)}{p(f_i = f_i(t))p\left(f_j = f_j(t')\right)} \quad (11)$$

The difference in probability between WP and P is $p(.)$. The Mutual Information (I) among the *i*th NWP factor and WP and the "*I*" between the (*i,j*) factors of NWP are represented by $I(f_i,\ P)$ and $I\left(f_i,\ f_j\right)$. $I = 0$ if the two variables are independent. If the randomness of the two variables is the same '*I*', their entropy is equal.

Minimum Redundancy and Maximum Relevance (mRMR)-Based Feature Selection

The mRMR algorithm [34] seeks to find an ideal set of SP-NWP factors that maximizes SP-NWP's relevance to a response variable P. It reduces WP-NWP, which stands for SP-NWP redundancy, wherein SP-NWP and WP-NWP are defined by mutual information I: Equations (12) and (13)

$$V_{S_{MWP}} = \frac{1}{\left|S_{NWp}\right|} \sum_{f_i \in S_{MWP}} I(f_i, P) \quad (12)$$

$$W_{S_{MWP}} = \frac{1}{\left|S_{NWP}\right|^2} \sum_{f_i \cdot f_j \in S_{MWP}} I\left(f_i, f_j\right) \quad (13)$$

Whereas SP-NWP is the number of factors within WP-NWP, a subset of the SP-NWP factors, WP-NWP is the number of factors in the NWP factors. For the mRMR Feature Selection (FS) method to work with temporal data, the data needs to be flattened into one matrix ahead of time. This could lead to the loss of crucial information within temporal data. This study uses the Modified Minimum Redundancy and Maximum Relevance (M-mRMR) method, which keeps the notion of the mRMR by maximizing the objective function, incorporating relevance and redundancy, yet adapts to control multivariate temporal data without flattening.

The temporal dataset with N cases is $D = \{X_i,\ c_i\}_{i=1,\ldots,N}$. G pragmatic NWP variables are assessed at T time; for example, I is represented by $X_i \in R^{G \times T}$. The case "I" is represented by the class as $c_i \in \{1, \ldots, K\}$. Call the $N \times T$ matrix of NWP data for the jth factor $g_j \in R^{N \times T}$, $j = 1, \ldots, G$. This work constantly computes the F-statistic to

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

represent the relevance of an NWP factor g_i and then combines these inputs using a suitable aggregation operator, in this case, the arithmetic mean (Algorithm 2).

Algorithm 2 M-mRMR	
Step 1:	Initialize $S_{All} := \{1, 2, \ldots, G\}$, $S := \varnothing$, $S_\alpha := \varnothing$;
Step 2:	While $g_j \in \mathbb{M}^{N \times T}$ Do:
Step 3:	The F-statistic values: $F\left(g_j, c\right) = \frac{1}{T}\sum_{t=1}^{T} F(g_j^{(t)}, c)$;
Step 4:	End Do;
Step 5:	$\mathbb{R} := Roundoff(\alpha G)$;
Step 6:	while $i < \mathbb{R}$ do:
Step 7:	$S_\alpha := S_\alpha \cup \underset{j \in S_{All}/S_\alpha}{Argmax} F\left(g_j, c\right)$;
Step 8:	End Do;
Step 9:	$S := \underset{j \in S_{All}}{Argmax} F\left(g_j, c\right)$;
Step 10:	For $len(S) < m$ Do:
Step 11:	While $k \in S_\alpha / S$ Do:
Step 12:	$S' := S \cup k$;
Step 13:	$V_{S_{MWP}} = \frac{1}{\left\lvert S_{NWP} \right\rvert} \sum_{f_i \in S_{MWP}} I(f_i, P)$;
Step 14:	$W_{S_{MWP}} = \frac{1}{\lvert S_{NWP} \rvert^2} \sum_{f_i \cdot f_j \in S_{MWP}} I\left(f_i, f_j\right)$;
Step 15:	End While;
Step 16:	$S := S \cup \underset{k}{argmax} \frac{V_F(g_k)}{W_{dtw}(g_k)}$;
Step 17:	End For;
Step 18:	Return S;

The top six weather factors are chosen as NWP factors because they have a strong link to power and are unlike other NWP elements.

This study employs CNN and physics-constrained LSTM as PMs, and the OWAWA operator is used to weigh the two models. CNNs, which are a popular Image Recognition Method (IRM), work well for dynamic methods that predict features. Because the LSTM is good at learning over time, it is reasonably accurately learning how to map NWP components to WP. Finally, using the OWAWA operator, a combination PM for short-term WPF is constructed.

- The Ordered Weighted Averaging—Weighted Average (OWAWA) Operator

The class of average aggregation functions includes Ordered Weighted Averaging (OWA) functions. They differ from weighted means, considering how the weights are related to the magnitude of the inputs rather than the specific inputs. For example, all inputs are comparable, and the relevance of each input is defined by its value.

OWAWA's operator is a new model that combines the OWA and weighted average operators into a single formula. Its key benefit is that it may unite both ideas while considering their relative relevance in the aggregate process. The following is a list of possible definitions.

An OWAWA operator of length 'n' is a mapping $OWAWA : R^n \to R$ that has an associated weighting 'W' with $w_j \in [0, 1]$; $\sum_{j=1}^{n} w_j = 1$, Equation (14):

$$OWAWA(a_1, a_2, \ldots, a_n) = \sum_{j=1}^{n} \widehat{v}_j b_j \tag{14}$$

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

where b_j is the jth greatest of the a_i and each argument of the a_i has an associated weight (WA) v_j with $\sum_{j=1}^{n} v_j = 1$ and $v_j \in [0, 1]$, $\hat{v}_j = \beta w_j + (1 - \beta)v_j$ with $\beta \in [0, 1]$, where v_j is the weight (WA) v_i ordered according to b_j, that is, the jth greatest of the a_i. This work receives the OWA operator if $\beta = 1$ and the WA if $\beta = 0$. The OWAWA operator achieves features such as those of traditional aggregation operators. It is worth noting that this work distinguishes between ordered layers and extends them using mixture operators, among other things.

This method has become common recently and merges two WPF methods in this study. Traditional combination PMs have different weighted average coefficients, so each PM's weighted average coefficient is stable throughout time points within that sample interval. The same PM may behave differently over time, with maximum prediction accuracy at one point and less prediction accuracy at another. A new integrated short-term WFM must be presented based on an OWA operator. Each PM is weighted in the combined model based on their prediction accuracy at each point in time. To some extent, the collective model avoids the problem of less prediction accuracy receiving more weight, whereas the method with maximum accuracy sometimes receives more weight.

- Physics-Constrained LSTM Model (PC-LSTM)

The PC-LSTM is designed using domain knowledge, and PV physical principles address the problems of modern Machine Learning (ML) algorithms, which are used on large amounts of data without taking physical laws into account (Figure 4). In creating the PC-LSTM, three types of restrictions (marked *as Cons. #1*, *#2*, *#3*) are used. The Data Filtering Module (DFM) is the initial module, and it divides the incoming data into distinct periods based on a flag variable. It filters training data to avoid physically improper forecasts, such as positive energy production at night, during training and testing. The PC-LSTM is based on global data or a basic concept of PV.

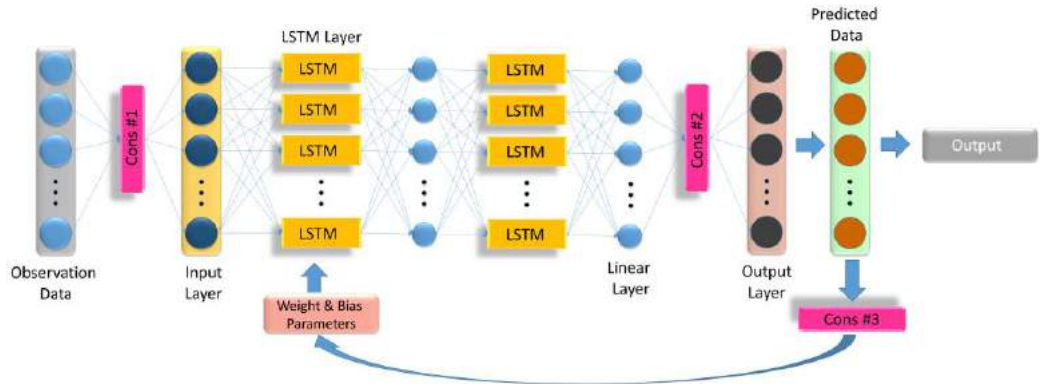

Figure 4. PC-LSTM architecture with three constraints.

PV panels near the ground surface gather solar energy, which is crucial for power generation. As a result, it is critical to mark periods with positive SP on the ground. Using hourly Surface Energy (SE) values, the DFM does this automatically. During training, the model only uses data from the marked periods. In the prediction step, on the other hand, the resulting PV output will be computed correspondingly for periods when SE is predicted to be '0'. The efficiency of the PC-LSTM is increased to some extent by using fewer data points for model training. The Clipping Module (CM) is the second constraint included in the PC-LSTM; it is used to keep the model's output within a tolerable range during training and testing. Using natural science to analyse PV avoids physical obstacles such as negative power generation. The model output should be positive because PV should be physically greater than '0'. As a result, the PC-LSTM output, y_i, should satisfy the constraint in Equation (15).

$$\hat{y}_i := ReLU(NN(x_i; \theta)) \quad (15)$$

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

A rectified linear unit function is *ReLU*(•). When '*-ve*', the *ReLU* function returns '0'; when '+*ve*', it returns the input value.

- OWAWA-CNN-LSTM Forecasting Model

In this paper, the PC-LSTM and CNN-PM are applied. The generated value inside the OWAWA operator is the RMSE for such two models in different test cases (Figure 5). The formulation could remain unchanged from Equations (16)–(18):

$$P_t^{\mathrm{wf}} = \mathrm{OWAWA}A_W\left(\left\langle e_{\mathrm{PCLSTM},t}, P_{\mathrm{PCLSTM},t}\right\rangle, \left(e_{\mathrm{CNN},t}, P_{\mathrm{CNN},t}\right\rangle\right) = \sum_{j=1}^{2} w_j P'_{j,t} \quad (16)$$

$$e_{\text{PC-LSTM},t} = \left|\frac{P_{\text{PC-LSTM},t} - P_t}{P_t}\right| \quad (17)$$

$$e_{\mathrm{CNN},t} = \left|\frac{P_{\mathrm{CNN},t} - P_t}{P_t}\right| \quad (18)$$

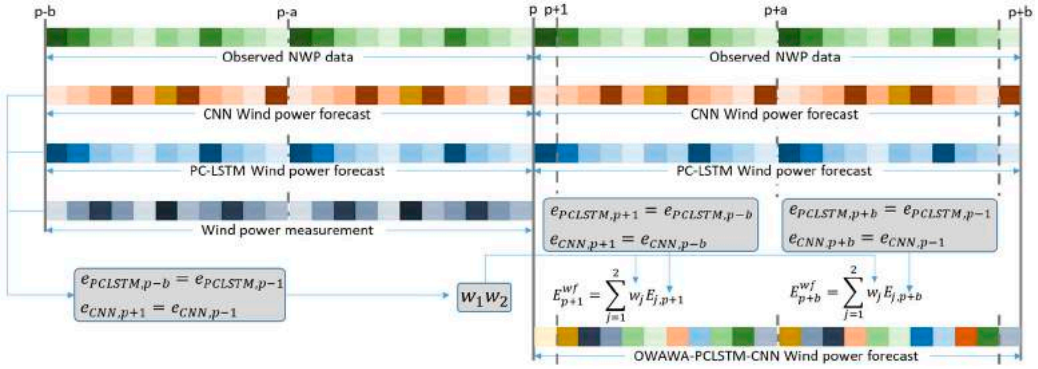

Figure 5. The OWAWA-CNN-PCLSTM integrated WPF model.

Pt is the measured WP at the time '*t*', as megawatts (MW). P_t^{wf} performs an OWAWA combined effectively with the WPF for point of time '*t*'. The WPF computed by the PCLSTM is $P_{\text{PC-LSTM},t}$, whereas the CNN model's computation of WPF is $P_{\mathrm{CNN},t}$. $e_{\mathrm{PCLSTM},t}$ and $e_{\mathrm{CNN},t}$, are the flaws of these two PMs at point of time '*t*'. $P'_{j,t}$ is the outcome of the WFM with the *j*th major error at point '*t*'. Solving the optimal control problem yields the weight values, w_j. $\mathrm{Min}S(W) = \sum_{t=1}^{N}\left(P_t - P_t^{wf}\right)^2$, Equation (19)

$$\text{s.t.} \begin{cases} \sum_{j=1}^{2} w_j = 1 \\ w_j \geq 0, j = 1,2 \end{cases} \quad (19)$$

As a principle for determining the weight constants, the size of squared errors (S/W) among Pt others P_t^{wf} is used.

The accuracy of other PMs, otherwise analysts, changes slightly the next day, as per [35]. The two models perform similarly when the weather is the same. The error dispersion of the two models differs when the current and predicted days have different weather classifications. As a result, the nearest day with the same weather type was selected instead of the previous day. The historical errors $e_{\mathrm{PCLSTM},t}$ and $e_{\mathrm{CNN},t}$ and values $P_{\text{PC-LSTM},t}$,$P_{\mathrm{CNN},t}$ for an adjacent day are identified beneath each weather type.

3. Modelling MOACO-Based DRP

Residential, industrial, and commercial electricity customers are studied in this section, and the continuity equation demonstrates the modelling for their behaviour. Constraints

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

show that each consumer's total energy reduction per hour should be less than or equivalent to the highest number of its offerings, e.g., Equations (20)–(22)

$$RP(r,t) = RC(r,t) \cdot \zeta_{r,t}\ , RC(r,t) \leq RC_t^{max} \tag{20}$$

$$CP(c,t) = CC(c,t) \cdot \zeta_{c,t}\ , CC(c,t) \leq CC_t^{max} \tag{21}$$

$$IP(i,t) = IC(i,t) \cdot \zeta_{i,t}\ , IC(i,t) \leq IC_t^{max} \tag{22}$$

where the residential, profitable, and business consumers counts are 'r', 'c', and 'i'; in period 't', the proposal of energy load minimization by all consumers is $RC(r,t)$, in period 't', $CC(c,t)$, and $IC(i,t)$ are the load reduction proposed by all consumers. In time 't', the proposal of maximum load minimization by all consumers is $RC_t^{\max}$, CC_t^{max}, and IC_t^{max}; the $RP(r,t)$, $CP(c,t)$, and $IP(i,t)$ are denoted by $\zeta_{r,t}$, $\zeta_{c,t}$, and $\zeta_{i,t}$. For the proposed load reductions, the cost of load minimization for residential, marketable, and business users in period 't' is reproduced.

3.1. Objective Functions

Price-and incentive-based DRP are the two types, with each group divided into subgroups depending on the consumer's engagement in modifying their purchasing habits. Because incentive-based liability programmers deal with price signals and are therefore optional, assessing the DRP based upon incentive payments and modelling that on enabling retailers' packages, given the lower quantity of requests, is shown in Figure 6.

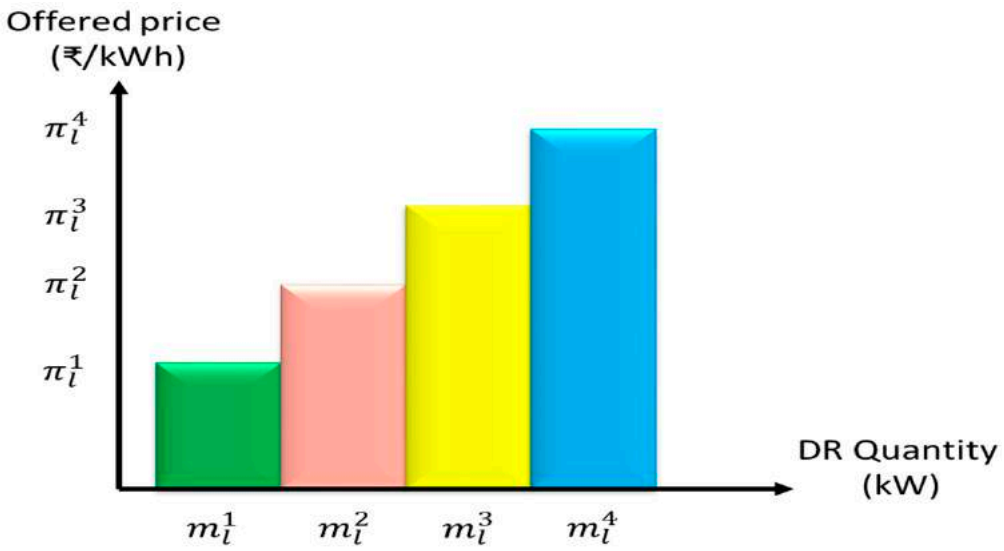

Figure 6. The Package of DRP's Offers.

With scattered producing resources such as WP and SP, this study will use a Multi-Objective Stochastic Model (MOSM) to assess operation costs and emission levels. Furthermore, DRPs based on incentive-based payment will minimize the uncertainty caused by the unpredictability of WP and SP resource behaviour throughout a 24-h planning horizon. In these schemes, responding to demands is categorized as residential, industrial, or commercial. Figure 7 shows the proposed optimization model.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

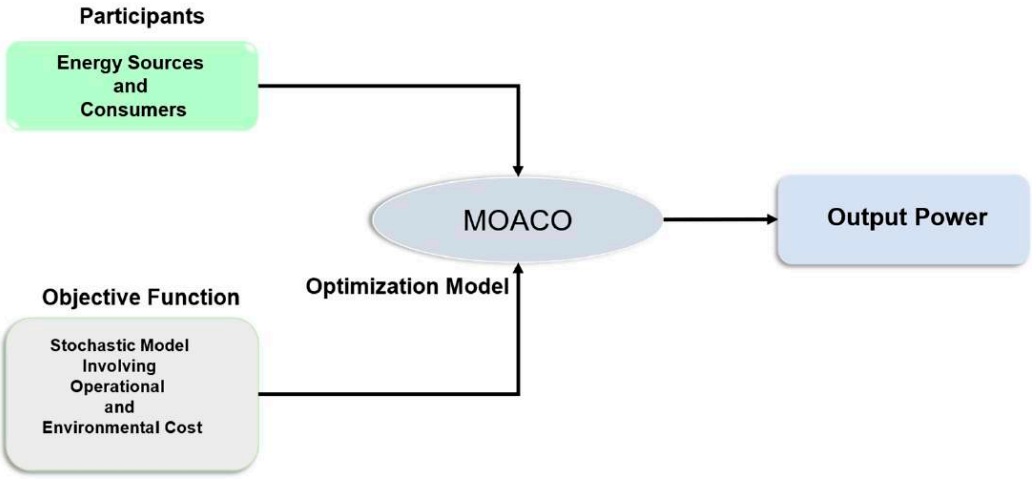

Figure 7. The Optimization Model.

3.2. Operational Cost Function

Unpredicted operating costs are estimated by evaluating and understanding the chance for a scenario, Pr_s, even in the '*t*' period and the '*s*' scenario that are prejudiced by the probabilistic. This component of an operational cost function comprises the cost of power savings due to DRP, and charges are linked to the Value of Lost Load (VOLL) and Expected Energy Not Served (EENS) to consumers.

$$Minf_1(X) = \sum_{t=1}^{T} F^{Cost}(t) = \sum_{t=1}^{T} COC(t) + \sum_{t=1}^{T} \sum_{s=1}^{S} Pr_s \times UOC_s(t) \quad (23)$$

wherein Pr_s is the possibility for scenario '*s*'. The operative costs, Equations (23) and (24), are confident and uncertain.

$$\begin{aligned} COC(t) &= \sum_{i=1}^{N_{DG}} \left[P_i(t)\pi_i(t)I_i(t) + SU_i(t)|I_i(t) - I_i(t-1)| + RC_i^{DG}(t)\right] \\ &+ \sum_{j=1}^{J} RC_j^{DR}(t) I_{Buy}(t) P_{Grid\text{-}Buy}(t)\pi_{Grid\text{-}Buy}(t) - I_{Sell}(t) P_{Grid-Sell}(t)\pi_{Grid-Sell}(t) \\ UOC_s(t) &= \sum_{i=1}^{N_{DG}} C_{i,s}^{DG}(t) + \sum_{j=1}^{J} C_{j,s}^{DR}(t) + ENS_s(t) \times VOLL(t) \end{aligned} \quad (24)$$

where during the '*t*' period, the output power and fixed cost for the *i*th unit's amount are indicated by $P_i(t)$ and $\pi_i(t)$; during the *t*th period, the ON/OFF mode of the *i*th DG is represented by binary $I_i(t)$; during the *t*th period, the running and shut-off costs for the *i*th unit are represented by $SU_i(t)$; the *i*th DG and DRP for the *j*th load's reserve costs are RC_i^{DG} and RC_j^{DR}; in period '*t*', the size of exchange power with utility is represented by $P_{Grid-Buy}(t)$ and $P_{Grid-Sell}(t)$; during the '*t*' period, in the open electricity market the suggested cost for exchange power with utility is indicated by $\pi_{Grid\text{-}Buy}(t)$ and $\pi_{Grid\text{-}Sell}(t)$; during the *t*th period in the *s*th scenario, the *i*th DG unit's running cost and the cost incurred for load minimization furnished by the *j*th DRPs are indicated by $C_{i,s}^{DG}(t)$ and $C_{j,s}^{DR}(t)$. At the '*t*' period and Value of Lost Load (VOLL) at the *t*th period, the Expected Energy Not Served (EENS) is $ENS_s(t)$ and $VOLL(t)$. At each DG, the battery's charge and discharge power and the switching of active power with the challenging grid produced by active power are included; $X^T = \{X_1, X_2, \ldots, X_T\}$ is the variable's state vector.

Regarding operational costs, DGs and DRP are reliable sources of reactive energy that make up for the lack of RE, SP, and WP. So, the DG is considered offline because its ground state is turned on to run standby power. As a result, the first part of the operating cost functions uses the fixed and start-up costs of DGs with a probability of one. In other words, when a situation in ON/OFF real-time mode happened, its DG stayed unchanged throughout the strategic planning process and power output was consumed only as per the day's preset parameters. So, this reversing payment will not change in any real-time

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

event of every scenario; therefore, the reserving cost is given a probability at the beginning of the objective function.

3.3. A Prototype of a Smart Grid System

The microgrid comprises DGs, energy reserves, and load systems that can run independently through the area's main SG [36]. Its development remains a component of the SG notion; given the benefits of SG, such as lower energy costs and increased system dependability and safety, it is apparent that microgrids and SGs have common goals [37]. Furthermore, SG technologies are required for benefits such as green technology development and DRP microgrids. The SG analyses the following consumers: residential, business, marketable, and RES, such as Micro-Turbines (MT), Wind Turbines (WT), PV cells, Fuel Cells (FC), and battery and diesel generators. This SG transfers energy with the utility [38,39].

MOACO Algorithm

Equal inequalities and constraints should be solved concurrently in Multi-Objective Optimization Problems (MOOP) since there are many conflicting objective functions, Equation (25).

$$\begin{array}{c} Min\ F(X) = [f_1(X),\ f_2(X), \ldots, f_n(X)]^T \\ Subject\ to: \begin{cases} g_i(X) < 0 & i = 1, 2, \ldots, N_{ueq} \\ h_i(X) = 0 & i = 1, 2, \ldots, N_{eq} \end{cases} \end{array} \quad (25)$$

where $F(X)$ is an objective function and 'X' is an increment variable, fi(X) is the 'i' objective function, $g_i(X)$ and $h_i(X)$ are equality and variation constraints, and 'n' is the number of objective functions. The possible solution for an MOOP is X or Y. The first solution will win, followed by the next, or none will control anything. As a result, if the two preceding conditions are met, one solution, 'X', will control the other in an optimization problem, Equation (26).

$$\begin{array}{l} \forall\, j \in \{1, 2, \ldots, n\}, \quad f_j(X) \le f_j(Y) \\ \exists\, k \in \{1, 2, \ldots, n\}, \quad f_k(X) < f_k(Y) \end{array} \quad (26)$$

As a result, non-dominated search space results are used to find Pareto set solutions. Eventually, the solution is located among the non-dominated results in the collection (Algorithm 3).

Algorithm 3 MOACO	
Input:	Production volume, proposed energy price, DG operational and emission costs, the next day's mean, and variance of WS and SP, and apply for demand from the daily load curve
Step 1:	Obtaining the volume of WP and SP from the proposed statical model
Step 2:	Set value parameters, number of ants (NA), and iterations (M)
Step 3:	Generate a primary population as $X^T = [X_1,\ X_2,\ \ldots,\ X_T]$;
Step 4:	Calculate fitness function: $Minf_1(X) = \sum_{t=1}^{T} F^{Cost}(t) = \sum_{t=1}^{T} COC(t) + \sum_{t=1}^{T} \sum_{s=1}^{S} Pr_s \times UOC_s(t)$;
Step 5:	Initialize Pareto archive:= $\varnothing$;
Step 6:	Identify and separate non-dominated results, and store them in the Pareto archive;
Step 7:	Initialize all pheromone values to τ_0;
Step 8:	While $i < M$ Do:
Step 9:	While $j < NA$ Do:

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Algorithm 3 MOACO	
Step 10:	Identify new solution S using: $j = \begin{cases} \text{argmax}_{j \in S_k(i)} \left\{ [\tau(i,j)]^{\alpha} [\eta(i,j)]^{\beta} \right\} & \text{if } q \le q_0 \\ J & \text{otherwise} \end{cases}$ $P_k(i,j) = \begin{cases} \frac{[\tau(i,j)]^{\alpha} [\eta(i,j)]^{\beta}}{\sum_{w \in r_k(i)} [\tau(i,u)]^{\alpha} [\eta(i,u)]^{\beta}} & \text{if } j \in S_k(i) \\ 0 & \text{otherwise.} \end{cases}$
Step 11:	For each solution in the current ant population, measure the values of the corresponding objectives;
Step 12:	Apply to update local rule using: $\tau_{i,j}(t) = (1-\rho_l)\tau_{i,j}(t-1) + \rho_l \tau_0$;
Step 13:	End Do;
Step 14:	Update Pareto archive;
Step 15:	While non-dominated solution ∈ Pareto archive Do:
Step 16:	Apply to update global rule: $\tau_{i,j}(t) = (1-\rho_g)\tau_{i,j}(t-1) + \frac{\rho_g}{P(S)+CS(S)}$
Step 17:	End Do;
Step 18:	End Do;

4. NWP Simulation and Analysis

The SG taken into consideration is connected to the utility and includes three users: residential, industrial, and commercial, for which requirements and a daily load curve are provided (Figure 8). The prototype system has a total EC of 3246 kWh. The current market price for Indian Energy Exchange (IEX) is depicted in Figure 9. IEX initiated power trading in India and provided a digital platform for state electricity boards, power manufacturers, power traders, and open access consumers. The reserve cost of Conventional Energy (CE) sources is estimated to be 25% of the more profitable cost of energy generation. Hourly WS data are shown in Figure 10, sourced from the IMD Pune weather prediction website [40]. The solar cell in discussion seems to be a 30 kW Adani PV Module, made with P-type bifacial solar cells, characterised by 1000 and 200 $^{W}/_{m^2}$ on the front and rear sides. Figure 11 depicts the average hourly SP sourced through the "Solar Energy Centre, Ministry of New and Renewable Energy, Government of India" [41].

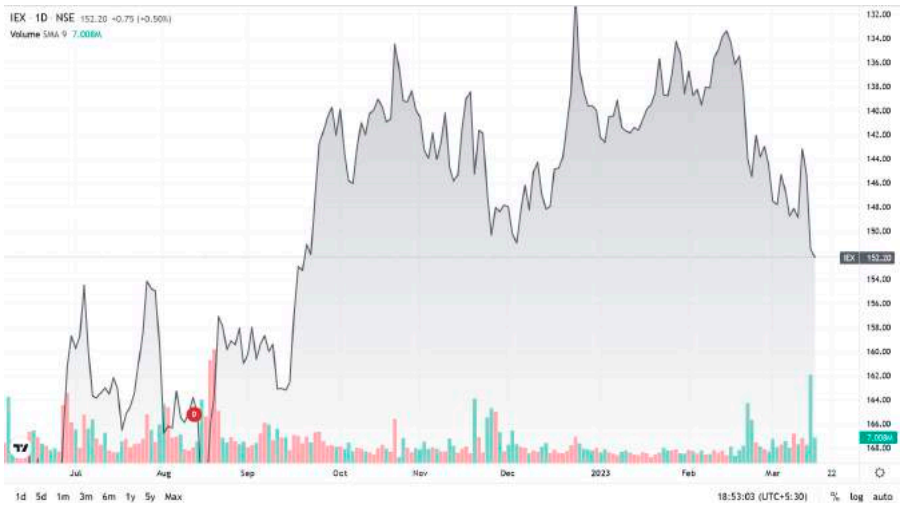

Figure 9. IEX market price in real-time (monthly chart).

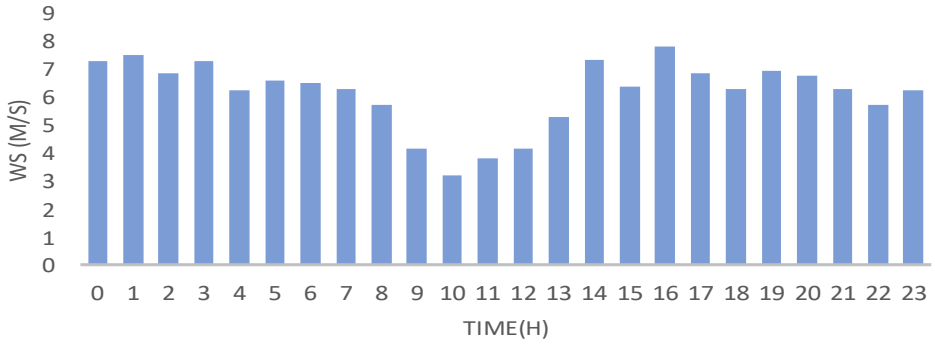

Figure 10. Hourly WS forecast.

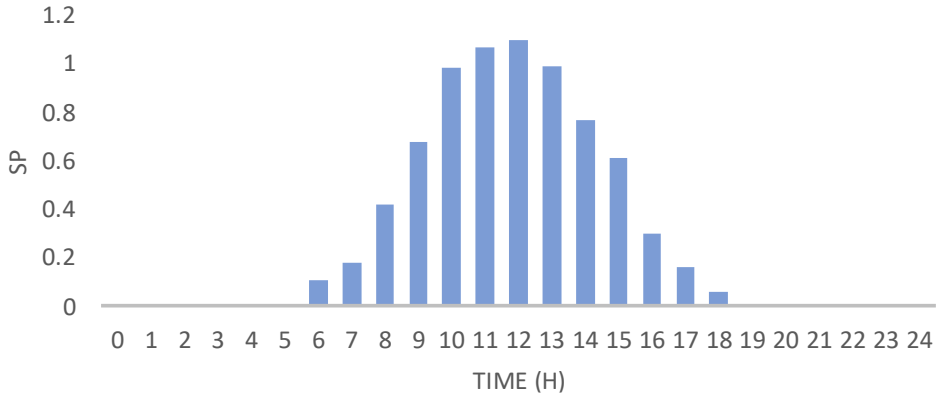

Figure 11. Hourly SP forecast.

With a power coefficient of 1, WT and PV systems adjust for reactive power locally by adding capacitors to related buses. The value of the lost load is estimated to be 1.54 $^{V}/_{kWh}$. A typical system with a 40 kWh battery charges from 10% to 100% of its capacity, with a 92% charge or discharge efficiency. Table 2 lists the DRP packages that are available. For DRP to be implemented, it is predictable that about 40% more consumers will enrol.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Table 2. Offered price package for DRP.

DRP-1	**kW**	**0–10**	**10–30**	**30–60**	**60–100**
	₹/kWh	1.5	1.8	2.15	4.5
DRP-2	**kW**	**0–10**	**10–40**	**40–60**	**60–80**
	₹/kWh	1.25	1.6	3.2	4.75

The problem is looked at differently to refer to how the energy level, reserve, and DR schedules affect operating costs and to clear up any confusion between WP and SP resources.

Case 1: Assuming the operational cost without DRP.

Case 2: Assuming the operational cost of DRP.

In all scenarios, power-producing units should be able to engage in the SG depending on their practical and commercial qualities, and in the presence of increased generation and demand, energy is exchanged only with the utility through a Point of Common Coupling (PCC). To verify the model's effects, the proposed model was created using MATLAB R2022a software.

Case 1: Considering the cost of operations without the proposed DRP: From here, the operational costs are minimised independently without considering the DR. Figure 12 illustrates the best power generation allocation for lower operating costs. It shows that the battery begins to be charged early in the morning when energy costs are low, and whenever energy costs are high, the utility obtains energy from SG, wherein CEs prioritize power usage only at the lowest quoted price. The outcomes in Figure 13 show that the SG does not seek SP and WP. As a result, when evaluating the reasonable operational cost, they will not get much consideration.

Case 2: Costs and functionality of operations using DR: With the help of DR, operating costs are reduced independently. Figure 14 demonstrates the optimal power generation unit allocation for reducing operational costs. Although SP generation decreases from 4.54 to 3.15 kW, WP generation in the DRP decreases from 8.02 to 7.41 kW. These programs reduce SP and WP generation from 47.68 to 44.65 kW and 86.10 to 84.32 kW, respectively.

Figure 15 shows how much energy a WT and solar cell produce when operational costs and DR are considered. Figure 16 shows that using DRPs limits the amount of WT and solar cells that can be made while also shifting demand from peak to off-peak times. When consumers take part in the DRP and say they will use less power at a specific time, the system operator can lower the power of the generating units.

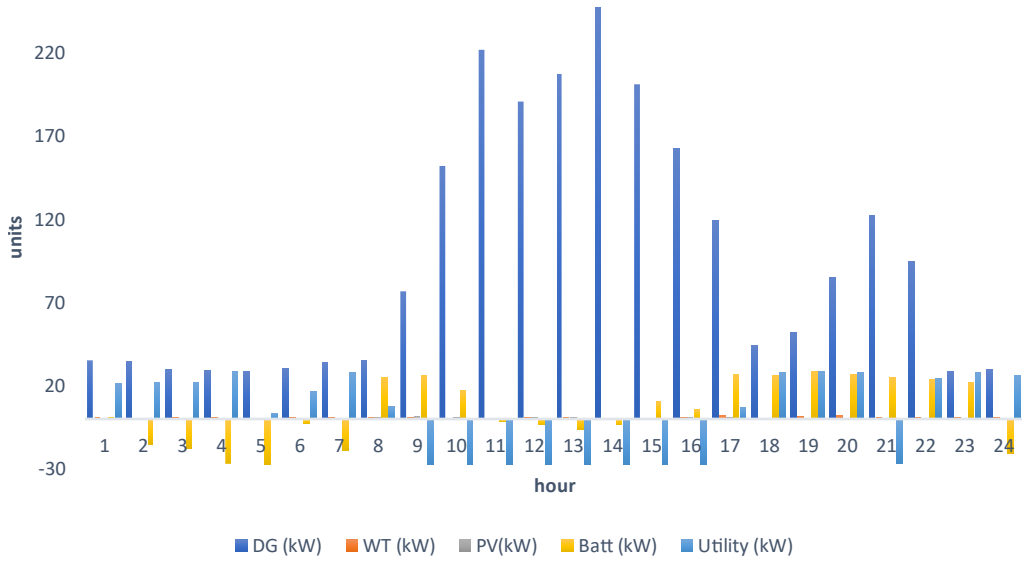

Figure 14. The operation cost of objective energy resource scheduling with DR.

The performance evaluation of MOACO is shown through a comparison of standard deviation. Out of 50 runs, it has a minimal standard deviation of 1 unit. Additionally, the computational speed is faster, such as 0.5 ms.

To validate the results, two more algorithms in the literature have been taken to solve the problem as given in Table 3. We have implemented Multi-Objective Flower Pollination Algorithm (MOFPA) [23] and Multi-objective Golden Flower Pollination Algorithm (MOGFPA) [42] to validate the MOACO results. Comparatively, the standard deviation of MOACO is a lot less. At the same time, computation time is faster than the other two algorithms, as shown in the Figure 17.

5. Conclusions

The optimal demand-side management for the Smart Grid (SG) was implemented in this work by treating the Demand Response (DR) as the compensation for uncertainty produced by Wind Power (WP) and Solar Power (SP) generation in an optimization function with two conflicting goals. In numerous scenarios, the microgrid's overall operational cost was assessed. Furthermore, Deep Learning (DL)-based Prediction Models (PM) for assessing WP and solar cell power generation were reported. The potential of energy exchange was envisaged for improved operation of the SG. Consumers are predicted to be engaged in DRPs based on incentive payments to manage consumption. To solve the given model and provide an optimal response, the MOACO method was applied. The simulations revealed that if customers employ DR and address production losses caused by uncertainty in WP and SP, it will reduce operating costs. In the future scope of research, this could be enriched with vehicle-to-grid techniques for optimal energy saving and management. Aggregator operations would also be considered for efficient operating conditions of the SG.

An Incentives Planning Framework for Residential Energy Retrofits: A Life Cycle Thinking-Based Analysis under Uncertainty

Tharindu Prabatha, Kasun Hewage * and Rehan Sadiq

School of Engineering, University of British Columbia (Okanagan Campus), 1137 Alumni Avenue, Kelowna, BC V1V 1V7, Canada

Abstract: Building energy retrofits can reduce emissions and increase cost savings. Some retrofits that can deliver higher emissions savings are not popular due to a lack of economic justifications. Financial incentives can be used to change buyer perception around such retrofits. This study proposes a framework to identify the best-performing retrofit strategies for a given building cluster and the optimal incentive amounts to promote the chosen strategies, accounting for uncertainties, stakeholder priorities, and budget constraints. The proposed framework was demonstrated using a case study complemented with policy insights. Life cycle cost savings and capital cost significantly impact retrofit purchase decisions. Case study results showed that retrofitting houses heated with electricity can produce significant cost savings. However, adopting energy-conscious behaviours in houses heated with natural gas and injecting renewable natural gas into the gas supply can produce two times more emissions savings achieved by any retrofit strategy applied to an electrically heated house. This indicates the need for adopting performance-based incentives over the prescriptive approach to reward occupant efforts in addition to asset performance. Despite potential life cycle cost savings, incentives must be complemented with low-interest loans to promote retrofit strategies carrying higher capital costs.

1. Introduction

Climate change is not identified as a future crisis anymore. Leading scientific bodies such as NASA acknowledge that climate change's impacts are already affecting the world [1]. The inter-governmental panel on climate change (IPCC) indicates that the associated environmental impacts would be beyond repair if the global temperature increases 1.5 °C over pre-industrial temperatures [2]. IPCC advocates curbing anthropogenic greenhouse gas (GHG) emissions to avoid the predicted climate adversities and identifies the building sector as a key area that can support this as it accounts for 12% of anthropogenic GHGs and 40% of the energy use in the world [2–4].

In response to these rising challenges, climate leaders such as British Columbia (BC), Canada developed innovative policy tools such as BC Energy Step Code to reduce the environmental impacts of new constructions [2]. However, improving the performance of existing buildings constructed to less stringent energy efficiency standards remains a challenge [3].

Retrofits are commonly used to improve the energy performance of existing buildings. Energy retrofits lead to economic, environmental, and indoor environmental quality (IEQ) performance enhancements [4]. Occupants can benefit from operational cost savings and improved IEQ [5]. In addition, building owners can benefit from the property value increases. In the bigger picture, retrofitting projects can support national climate change

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

mitigation initiatives and local economies through emissions savings and job creation [6]. However, financial pressures such as high life cycle costs (LCC) and capital costs (CC) and lack of economic justifications can reduce the community acceptance of retrofits [7,8]. Therefore, building owners have to be not only guided and educated but also need to be provided with an economic rationale to adopt these interventions.

Carbon taxing and emissions capping are used to minimize the use of energy generated using higher emissions sources [9]. However, regionally implemented penalties such as provincial carbon taxes can pose challenges to local industries competing in the global market due to increased production costs [10]. Moreover, energy affordability issues resulting from penalties can create social predicaments that could result in a backlash against government-led clean energy promotion and climate change mitigation initiatives [11,12]. Therefore, bringing forward the penalties as the first step can hinder the success of energy retrofit promotion campaigns. Moreover, emissions penalties and caps fail to promote energy conservation opportunities associated with cleaner energy sources. Therefore, promoting performance improvements with financial incentives is more appropriate to drive industries and the public towards energy-efficient technologies and cleaner energy sources in the initial stages [13,14]. When the community is ready for more clean energy uptake and equipped with energy efficiency practices, penalties can be slowly introduced in an incremental approach. Considering the importance of incentives/rebates in promoting building energy retrofits (BER), this article focuses on financial incentives planning for energy retrofits.

A Compendex database search in January 2022, using "residential", "building", "energy", "retrofit", and "incentive" as keywords yielded seventy-three research articles. Diakaki et al. developed a retrofit selection algorithm considering annual energy use, annual emissions, and capital cost employing a multi-objective solution methodology [15]. Bonomolo et al. proposed an approach to identify the cost-optimal lighting retrofits accounting for daylighting opportunities [16]. Zang et al. proposed a Pareto optimization approach for residential retrofit selection [17]. Ruparathna et al. developed an economic evaluation approach for retrofit evaluation [18]. All the reviewed literature contributed to improving retrofit selection processes. However, the current approaches did not address either one or a few of the following aspects of community retrofit planning: life cycle costing and emissions, addressing the uncertainties, contradicting decision priorities, and promotion of retrofits through financial incentives.

Findings from the literature review motivated the authors to investigate the need for a comprehensive strategy to identify the best retrofit strategies and optimal incentive levels to promote the best-performing retrofit packages/strategies under uncertain conditions. In addition to the literature review, the authors communicated with experts from local municipalities, construction companies, building management agencies, utility providers, and Natural Resources Canada to establish the need for an energy retrofits and incentives planning mechanism. All stakeholder groups echoed the need for a decision support tool enabling standardized incentives and energy retrofits planning strategy to achieve the climate action goals of the existing buildings sector. Identified research gaps related to building energy retrofits and incentives planning are summarized below:

(1) No comprehensive models have been developed for quantitatively determining incentive amounts for building energy retrofits, and the multi-stakeholder nature of the problem is overlooked [13,19,20].
(2) Life cycle emissions (LCE) are overlooked in retrofits and financial incentives planning. Embodied emissions are often neglected due to the singular focus on operational emissions [21].
(3) Uncertainties related to building retrofits and the external environment have been largely neglected in past studies in retrofit strategy and incentives planning [13,22]. Moreover, the sensitivity of the residential energy retrofit project outcomes to the operational conditions and macroeconomic parameters has not been sufficiently investigated.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

This study addresses the research gaps discussed above regarding its academic merit by proposing an incentive/rebate planning strategy for BERs to maximize environmental and economic benefits under uncertainty while accounting for budgetary constraints and stakeholder priorities. More importantly, it provides a much-needed quantitative decision-making model that can be used by different levels of government and non-governmental organizations to identify the optimal incentive levels with the limited budget in hand. Moreover, the proposed retrofit selection framework can be used by individual building owners/contractors to determine the best retrofit strategies under uncertainty for their buildings.

The proposed approach was demonstrated using a Canadian case study. The sensitivity of different retrofit strategies to uncertainties in energy supply and building operational conditions, macroeconomic parameters, and alternate decision priority scenarios was evaluated based on the case study results. However, the proposed approach can be used worldwide by altering the inputs. Inputs to the model include the energy-saving potential of different retrofit strategies (generated from the energy simulation software), energy cost and emission factors, retrofit-related cost factors (e.g., capital and maintenance costs), decision priorities, and constraints. These inputs can be selected according to the local conditions and the proposed retrofits selection and incentives planning algorithm can be applied irrespective of the location or building type.

1.1. Promoting Building Energy Retrofits

Opportunities and challenges associated with BERs can be better understood using the eco-efficiency classification presented in Table 1.

Table 1. Eco-efficiency classification [13].

	LCE Savings	LCC Savings
Priority retrofits (PR)	Yes	Yes
Secondary retrofits (SR)	Yes	No
Tertiary retrofits (TR)	No	Yes/No

Retrofits that require energy source switching from a low-emission source to a high-emission source and retrofits that create higher embodied emissions than operational emissions savings fall under tertiary retrofits. Nevertheless, some TRs can produce LCC savings.

PRs simultaneously produce emissions and cost savings [13]. If the payback periods are sensible, building owners can be easily convinced to implement PRs, making them effective options for government emission reduction initiatives. High capital costs can be a barrier for PRs, preventing building owners from adopting them [23]. In such situations, a loan scheme can be introduced to assist the building owners in implementing such retrofits [17,24]. However, stakeholders are generally reluctant to adopt loan schemes due to the high administrative workload and pre- and post-performance uncertainties [25]. Administrative issues can be mitigated by involving energy performance contracts and energy services companies (ESCO).

Emissions reduction potential alone will not likely motivate building owners to adopt retrofits. Therefore, a business case needs to be created by financially incentivizing energy-efficient technologies and/or penalizing the cheaper alternatives that depend on emissions-intensive energy sources to make a business case for SRs [9,26].

1.2. Incentivizing Energy Retrofits

Incentivizing energy retrofits can be done following either a prescriptive or a performance-based approach, and each approach has unique positives and negatives [12]. In the prescriptive approach, the implementation of a prescribed retrofit is incentivized [27]. In practice, the incentive provider checks a predefined document, such as the bill of sale, and provides the incentive based on that. Prescriptive incentives are easier to implement compared to performance-based incentives [28]. From the receivers' perspective, this

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

boosts confidence in retrofit investments, as they are certain about the incentive to be expected once the retrofit is installed. This is easy to implement from the incentive issuers' perspective as less administrative work is involved. Importantly, the actual energy and emissions performance of a retrofit's post-installation phase highly depends on locational parameters, including weather and energy prices [13]. Moreover, it can significantly change with behavioural practices such as setting the heating and cooling temperatures and occupancy schedule. Therefore, if the prescriptive approach is followed, the outcomes must be evaluated based on local conditions because provincial or national-level generalizations may promote unsuitable energy retrofits for a given municipality or region. On the other hand, the prescriptive approach does not have the leverage to motivate building occupants to adopt energy-conscious behaviour during the post-retrofit period, as the incentives are issued upfront. This challenge can be addressed to a certain level with awareness programs.

In the performance-based approach, incentives are offered for achieving a certain goal concerning energy use/intensities or emissions savings/intensities based on a predefined performance benchmark. In this approach, the building owners are given the flexibility to reach the goal by applying any retrofit combination rather than being limited to predefined options. This flexibility for innovative decision-making is the strength of the performance-based approach. Moreover, it pays attention to the behavioural component of building energy performance. In contrast to the prescriptive approach, the owners are compelled to adopt energy-conscious behaviour to reach better performance levels to secure higher incentive amounts [29]. However, assessing the pre- and post-retrofit performance of an existing building and predicting the future outcomes of design decisions can be quite challenging when issuing this type of incentive [30].

1.2.1. Performance Assessment

There are two main methods commonly used for building energy performance assessments. The first approach uses energy bills for performance evaluations [19]. When employing this approach, it should be noted that energy demand can significantly vary with other factors such as weather, occupancy schedule, and occupant behaviour, which are independent of the energy efficiency of the building. This method needs at least one-year worth of pre- and post-retrofit energy records to evaluate the performance of the building/buildings under evaluation. Collecting energy records and accommodating missing utility bills can be quite challenging [31]. Alternatively, energy simulations can be used to evaluate the operational performance of retrofits [13]. The simulation assumptions can significantly affect the accuracy of the predicted retrofit performance, leading to many uncertainties [32]. ASHRAE energy simulation guidelines for existing buildings or local standards can be followed to minimize the errors created by assumptions [33,34].

1.2.2. Incentives Planning

Compared to the challenges associated with the penalties, rebates and subsidies are deemed better suited to retrofit incentivization initially [35]. Therefore, this study investigates incentive planning considering rebates and subsidies. However, incentive programs need viable financial models to keep the money flowing for continued operations and future sustainability. Therefore, penalties can also be introduced in the following phases to ensure the longevity of incentive programs.

Incentivizing energy retrofits aims to reduce the emissions associated with buildings. However, local governments and private sector organizations such as utility companies have only a limited budget for incentive programs. Therefore, identifying the best split of available funding among different retrofit options needing incentives is essential to maximize the emissions savings within the allocated budget from the incentive providers' perspective. Parallelly, building owners and contractors need to be provided with tools to determine the most suitable retrofit options for their situations to meet the required performance targets and maximize incentive benefits.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

In both situations discussed, selecting the best retrofit strategies and retrofits that need to be incentivized is challenging due to associated uncertainties and the exhaustive number of potential retrofit strategies that can be developed by combining alternative retrofit options [13]. Individual performance of retrofits can vary with the other retrofits combined with them. Moreover, the condition of the building and components needing replacement and the available budget greatly influence the building owner's decision-making. Therefore, the incentive providers cannot prescribe a single retrofitting strategy for a house. Ideally, incentive amounts proposed for individual incentives should be able to promote the top-ranked retrofit strategies (combinations) applicable for a given building or building cluster.

2. Materials and Methods

This study proposes a framework for selecting retrofit strategies and financial incentives to promote environmentally friendly BERs under uncertain conditions. Therefore, this study did not analyze tertiary retrofits (which deliver no environmental benefits). Figure 1 summarizes the proposed framework and methodology.

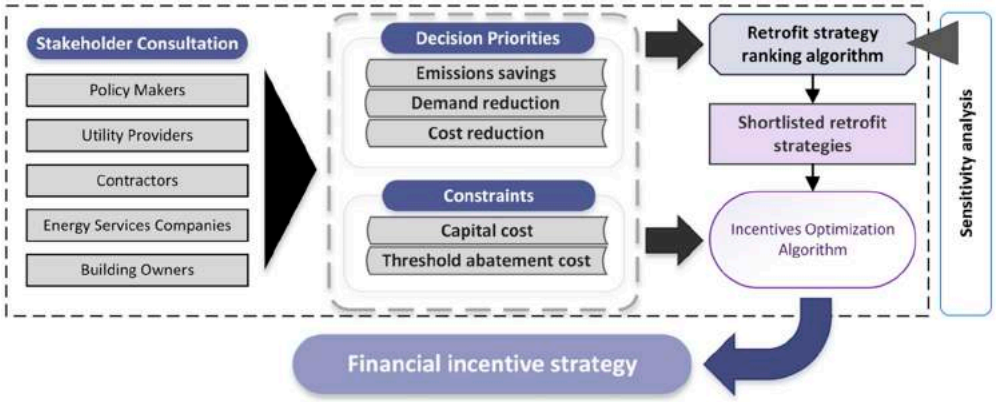

Figure 1. Retrofits selection and incentives optimization framework.

Decision priorities and constraints act as inputs to the retrofit selection and incentives optimization process. Stakeholder consultation sessions are recommended to identify the decision priorities and constraints associated with the incentives planning exercise for any community planning to employ this framework.

The next step of the proposed framework is to conduct a sensitivity analysis to identify the critical parameters that influence the performance of BERs. Results from the sensitivity analysis help model the uncertainties associated with the BER performance employing fuzzy numbers. The fuzzy-based BER performance information, decision priorities, and constraints feed into a fuzzy-multi-criteria options ranking algorithm to identify the best retrofit strategies that meet the decision priorities and constraints. This algorithm outputs the best retrofit strategies (combination of retrofits) for the given community.

The selected retrofit strategies move forward to the proposed incentive optimization algorithm. This algorithm determines the optimal financial incentive amounts needed to promote the chosen strategies. Both retrofit selection and incentives planning algorithms can be flexibly used at the individual building or community level by changing the inputs and constraints.

The proposed framework was demonstrated using a case study. Two representative buildings were selected as the base buildings for the case study. Commonly used BERs were identified based on published literature and other resources such as manufacturer data. The energy-saving potential of BERs was evaluated with HOT2000 energy simulation software (future users can choose the energy simulation tools applicable to their jurisdiction or application). All possible combinations of the retrofits with life cycle emissions reduction potential were considered in the evaluation. The evaluation results produced the best

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

retrofit strategies and optimal incentive amounts to promote the selected strategies in the case study location.

2.1. Sensitivity Analysis

BER performance predictions are sensitive to input parameters and assumptions. Therefore, a sensitivity analysis was conducted to understand the variations in the energy model outputs with the input parameters, including operational conditions and energy supply-related factors.

2.1.1. Sensitivity of Energy Demand to Operational Conditions and User Behaviour

Percentage energy demand change (PEDC) was against a percentage or an absolute change in input parameters, including the number of occupants, time at home, hot water demand and temperature, and space cooling and heating setpoints. The sensitivity analysis was conducted using the weather conditions in Kelowna, Canada. The sensitivity of energy demand to different input parameters can be more or less pronounced in harsher or milder climates compared to Kelowna. The results of the sensitivity analysis are presented in Section 4.1.1.

2.1.2. Sensitivity of Operational Cost and Emissions to Energy Price and Emission Factors

Depending on the grid energy mix, electricity can be cleaner than natural gas, but natural gas is generally cheaper in Canada. Energy cost and emission factors can be decisive parameters for source-switching decisions related to building heating and hot water systems. Therefore, operational cost and emissions were plotted against the energy sources' unit energy price and emission factor variations, respectively, to understand the potential impacts. Two energy price and emission scenarios were considered for this. Scenario 1 assumes that the electricity price and emission factor stay constant while the natural gas (NG) price and emission factor vary. Scenario 2 assumes that NG's price and emission factor remains constant while the price and emission factor of the electricity supply vary.

The operational emissions were calculated using Equation (1)

$$OE = \sum Demand_j \times EF_j \quad (1)$$

where

OE—Operational emissions ($kgCO_{2e}$)
$Demand_j$—Demand for j^{th} energy source (kWh)
EF_j—Emissions factor of jth energy source ($kgCO_{2,eq}/kWh$)

Similarly, the operational cost was calculated using Equation (2)

$$OC = \sum Demand_j \times UEP_j \quad (2)$$

where

OC—Operational cost ($)
UEP_j—Unit energy price of jth energy source ($/kWh)

Detailed results of this analysis are presented in Section 4.1.2.

2.2. Retrofit Performance Evaluation

The goal of the retrofit performance evaluation was to identify the best retrofit strategies to maximize the environmental and economic benefits. LCC and LCE were employed as economic and environmental performance indicators [13]. Retrofit performance can significantly vary with the uncertainties introduced by occupant behaviour, building operational conditions, energy price, and emissions factors [36–38]. Previous studies discussed the pros and cons of using fuzzy-based and probabilistic methods to address uncertainties [39]. However, most uncertain parameters in building-related decision-making do not

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

have sufficient data to develop probability distributions [19,39]. Moreover, fuzzy numbers can handle qualitative and quantitative inputs [40,41]. Using fuzzy numbers allows the proposed framework to be extended to include qualitative parameters such as user satisfaction, occupant health, and thermal comfort in future research. Considering the discussed advantages, the framework was developed using fuzzy-based methods, and fuzzy sets were used to model uncertainties in the model parameters [19,39].

Previous studies have evaluated the performance of the retrofits considering individual retrofits [13]. However, the performance of individual retrofits can change significantly due to performance interactions when combined with other retrofits. Therefore, all possible combinations of the retrofits that can produce emission savings (priority and secondary retrofits) were considered when evaluating the retrofit performance. The performance values of individual retrofits under these variable conditions and retrofit combinations were brought forward to the incentive optimization algorithm. The detailed retrofit evaluation process is discussed below.

2.2.1. Energy Performance

HOT2000 is currently used for energy simulations of small residential buildings in BC Energy STEP Code and EnerGuide [8,29]. HOT2000 (Version 11.3) was used in this study as it is the recommended software for Canadian residential energy studies. Natural Resources Canada (NRCan) developed the Housing Technology Assessment Platform (HTAP) to support energy analysts in handling large numbers of energy simulations [42]. Using the strength of HTAP and HOT2000, all possible combinations of the considered retrofit options were simulated. The simulation results were used to calculate the operational cost and emissions savings potential of retrofits in the subsequent steps.

Fuzzy numbers were used to represent the energy performance of the base buildings and the retrofit upgrades. The key parameters to which the energy use was sensitive were used to characterize the aforementioned fuzzy number. Energy simulations were conducted considering three operational conditions to define the Lower and Upper Bounds and the Likely Values of the said fuzzy numbers. The Likely Value was determined considering the nominal operational conditions from the study by Prabatha et al. [13]. The Lower and Upper Bounds were defined by varying the nominal operating conditions. Operational energy savings under each fuzzy value (i.e., Lower Bound, Likely Value, Upper Bound) were calculated using Equation (3).

$$OES_{i,j,k} = PreDemand_{j,k} - PostDemand_{i,j,k}; k \in [\text{Lower}, \text{Likely}, \text{Upper}] \quad (3)$$

where

$OES_{i,j,k}$—Operational energy savings of jth energy source by i^{th} retrofit scenario

$PreDemand_{j,k}$—Pre-retrofit energy demand for j^{th} energy source

$PostDemand_{i,j,k}$—Post-retrofit energy demand for j^{th} energy source by the ith retrofit combination

The fuzzy form of the operational energy savings is given below.

$$\underline{OES}_{i,j} = [OES_{i,j,Lower}, OES_{i,j,Likely}, OES_{i,j,Upper}] \quad (4)$$

This fuzzy number was combined with the emission factors and energy prices to evaluate the operational performance of the retrofit strategies.

2.2.2. Environmental Performance

Global warming potential is commonly used to indicate environmental impact in climate change mitigation activities [22,43]. Life cycle emissions have been previously used as an indicator of global warming potential and environmental performance [13,44,45]. Therefore, life cycle emissions ($kgCO_{2e}$) were selected as the environmental performance indicator. Three main components, including embodied, operational, and disposal emis-

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

sions, were considered in calculating the life cycle emissions of retrofits [13]. Embodied emission data from literature was adopted for this study [13]. Equation (5) was used to calculate the life cycle emission savings associated with each retrofit scenario.

$$\underline{LCES_i} = -\sum_{\delta=1}^{N} EE_{i,\delta} + \sum_{j=1}^{2} \underline{OES_{i,j}} \times \underline{EF_j} - \sum_{j}^{N} DE_{i,\delta} \quad (5)$$

where

$\underline{LCES_i}$—LCE savings resulted from ith retrofit scenario; (in fuzzy form)
N—Number of retrofits implemented in the ith retrofit scenario
$EE_{i,\delta}$—Added embodied emissions by the δth retrofit in the ith retrofit scenario
$\underline{OES_{i,j}}$—Operational energy savings of the ith retrofit scenario related to jth fuel (NG, E); (in fuzzy form)
$\underline{EF_j}$—Emission factor of the jth fuel (NG, E); (in fuzzy form)
$DE_{i,\delta}$—Disposal emissions of the δth retrofit in the ith retrofit scenario

2.2.3. Economic Performance

Life cycle cost (LCC) was used to evaluate the economic performance of different retrofit combinations accounting for capital, operational, and disposal costs [46]. The cost of equipment and installation was accounted for under the capital cost. RSMeans Building Construction Cost Database and Online vendor prices were employed in the costing. Equations (6)–(11) were adopted from Prabatha et al. for LCC calculations [13].

$$IC_{envelop,i} = \sum_{\forall\theta} IC(p,\theta) \times A_\theta; \theta \in [Walls, Roof, Windows, Doors, Foundation] \quad (6)$$

where

$IC_{envelop,i}$—Initial cost of the envelope of the ith strategy
A_θ—Area of the envelope component
$IC(p,\theta)$—Initial cost to implement pth modification option under the θth envelope component

$$IC_{EnergySystem,i} = \sum_{\forall q} ICE_q \quad (7)$$

where

$IC_{EnergySystem,i}$—Initial cost of ith system retrofit strategy
ICE_q—Initial cost of qth energy system retrofit component

$$CC_i = IC_{envelop,i} + IC_{EnergySystem,i} \quad (8)$$

where

CC_i—Total capital cost of ith retrofit strategy

$$OCS_i = \sum_{\forall j} OES_{i,j} \times C_j \quad (9)$$

where

OCS_i—Annual operational cost savings achieved by ith retrofitting strategy
C_j—Average unit cost of jth energy source

$$DC_i = (C_{LF} + F \times T \times C_T) \sum_{\forall\delta} W_\delta \quad (10)$$

where

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

DC_i—Disposal cost associated with ith retrofit strategy
W_δ—Amount of disposal waste (kg) produced by δ^{th} retrofit option removed
C_{LF}—Landfill cost per kg of waste
F—Number of trips to the landfill
T—The double distance between the landfill and the building (km)
C_T—The cost of transportation per kg of waste per km

$$\underline{LCCS_i} = -CC_i + \left(\frac{(1+r)^t - 1}{r(1+r)^t}\right).\underline{OCS_i} - DC_i \quad (11)$$

where

$\underline{LCCS_i}$—LCC savings resulted from ith retrofit scenario; (in the fuzzy form)
r—Discount rate
t—Project period

2.3. Performance-Based Retrofits Planning

LCCS and LCES were considered the key performance indicators (KPI) of retrofit performance, and they were calculated as fuzzy numbers to account for uncertainties. The relative importance of the LCCS and LCES can change depending on the priorities of the stakeholders. Policymakers and building owners are more interested in the LCES and LCCs, respectively. Importantly, a retrofit project is unlikely to proceed if the building owners' expectations are unmet. Therefore, it is essential to establish the relative importance of the KPIs based on a stakeholder survey in practical implementation. The relative importance of LCCS (W_1) and LCES (W_2) was changed from 0–100% to explore the impact of decision priorities on the outcomes (ensuring that the sum of the two weights is always 100%). The overall performance score of each retrofit combination was calculated as shown in Equation (12).

$$\underline{F_i} = W_1 \times \underline{LCCS_i} + W_2 \times \underline{LCES_i} \quad (12)$$

where

$\underline{F_i}$—Overall performance score of the ith retrofit scenario

$\underline{F_i}$ was calculated as a fuzzy number for all the retrofit strategies from 1 to n.

$$\underline{F_i} = \{x | f_{F_i}(x) > 0\}; i = 1, 2, \ldots, n \quad (13)$$

Maximizing and minimizing set method has been used for fuzzy number ranking in several previous studies [47,48]. This technique identifies the option closest to the best performance level and the furthest from the worst performance level as the best option. Based on this criterion, it ranks the retrofit strategies. This method is close to the fuzzy TOPSIS method, which is considered a reasonable approximation of the human decision-making process [43]. The normalizing method employed makes it possible to compare a large number of alternative solutions against each other. It also adapts the TOPSIS concept in a generalizable manner to a fuzzy environment, reducing the loss of fuzzy information [49]. Maximizing set (A) and minimizing set (B) are defined as shown in Equations (14) and (15), respectively. The membership of x to A and B is represented by $f_A(x)$ and $f_B(x)$, respectively [48].

$$A = \{(x, f_A(x)) | x \in R\} \quad (14)$$

where

$$f_A(x) = \begin{cases} \frac{x - x_{min}}{x_{max} - x_{min}} & , \quad x_{min} \le x \le x_{max} \\ 0 & , \quad otherwise \end{cases} \quad (15)$$

$$B = \{(x, f_B(x)) | x \in R\}$$

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

where

$$f_B(x) = \begin{cases} \frac{x - x_{max}}{x_{min} - x_{max}} & , \quad x_{min} \le x \le x_{max} \\ 0 & , \quad otherwise \end{cases}$$

Parameters used in $f_A(x)$ and $f_B(x)$ calculations are defined below.

$$x_{min} = \inf(S); \;\; x_{max} = \sup(S); \;\; S = \bigcup_{i=1}^{n} F_i$$

The right, left, and total utility values for each retrofit scenario were calculated as seen in Equations (16)–(18), respectively.

$$U_A(F_i) = \sup\left(f_{F_i}(x) \bigcap f_A(x)\right), i = 1, 2, \ldots, n \tag{16}$$

$$U_B(F_i) = \sup\left(f_{F_i}(x) \bigcap f_B(x)\right), i = 1, 2, \ldots, n \tag{17}$$

$$U_T(F_i) = \frac{U_A(F_i) + 1 - U_B(F_i)}{2} \tag{18}$$

The retrofit combination that produces the highest $U_T(F_i)$ is considered the best-performing retrofit strategy. Building owners and policymakers can use this method to identify the best retrofit strategies for a given building or a building cluster. If the requirement is to determine the best retrofit strategy for a given building, the effectiveness of alternative retrofit options will be modelled and ranked following the approach discussed above.

If the requirement is to identify the best retrofit strategies to be promoted in a community, a set of representative buildings will be selected. Then, the best retrofit strategies for those buildings will be identified using the proposed approach. Top-ranked retrofit strategies will indicate the best retrofit options and the building archetypes, providing the best opportunities to realize cost and emissions savings for the community.

2.4. Incentives Optimization

If incentives were assigned considering only the best retrofit strategy, some retrofit strategies having closer performance would be overlooked. Moreover, it is unlikely for all renovation projects across the community to choose the same retrofit strategy. Therefore, instead of incentivizing only one strategy, a set of top-performing retrofit strategies selected using the retrofits selection framework was considered for incentives planning. However, incentivizing retrofit strategies (combination of retrofits) is not practical as that increases the administrative burden on the incentive issuers and reduces the design flexibility for the incentive receivers (homeowners).

It was decided to incentivize individual retrofit options based on their appearance in top selected retrofit strategies to address the aforementioned challenges. The goal of the proposed incentive optimization approach was set as "to identify the best incentive levels that need to be assigned to individual retrofits to promote the top-ranked retrofit strategies".

As explained by Equations (12) through (18), the top-ranked retrofit strategies achieve the highest performance scores ($U_T(F_i)$). The total utility of all retrofit strategies was compiled in a row matrix U ($1 \times n$), where "n" is the number of strategies selected as suitable for incentivizing in the retrofit selection process discussed in Section 2.3.

Some retrofit strategies may not contain certain retrofits. The availability of individual retrofits in each retrofit strategy was represented in an availability matrix (A). A is a ($m \times n$) matrix where "m" is the total number of retrofit options available to choose from. The elements of the availability matrix were defined as shown in Equation (19).

$$A_{i,\delta} = \begin{cases} 1; \; if \; retrofit \; "\delta" \; is \; available \; in \; scenario \; "i" \\ 0; \; if \; retrofit \; "\delta" \; is \; not \; available \; in \; scenario \; "i" \end{cases} \tag{19}$$

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

If the retrofits were evaluated just based on the number of occurrences in the chosen retrofit strategy set, then a retrofit that appeared in a few top-ranked retrofit strategies would be incentivized similar to a retrofit that just made a similar number of appearances but in lower-ranked retrofit strategies. Therefore, to avoid the aforementioned issue, a performance index matrix P (m × n) was defined by elementwise multiplication of U and A, as shown in Equation (20).

$$P_{i,\delta} = A_{i,\delta}.U_i \tag{20}$$

The incentive amount assigned to individual retrofit options is the optimization variable and was represented by a (m × 1) matrix indicated by "IN" ($IN \, \epsilon \, R$). The objective function was defined as shown in $\epsilon \, R$ Equation (21).

$$Z = sum\left\{P^T.IN\right\} \tag{21}$$

Optimization problem:

The optimization problem was a maximizing problem with two constraints, as presented below. The incentive amounts that can maximize Z were selected as the optimal solution.

$$Z^* = \max\{Z\}$$

Bound to the following constraints:

i. The incentive amount shall not exceed the capital cost of the retrofit $IN_i \leq CC_i$
ii. Total incentives should not exceed the maximum budget allocation for incentivizing retrofits of the given building archetype

$$sum\{IN\} \leq IncentiveBudget$$

The optimization problem was modelled using the MATLAB linprog solver.

3. Case Study

Kelowna, Canada (Climate zone 5, heating degree days: 3000–3999) was selected as the case study location for demonstration purposes. NG and electricity are Canada's most common fuel types for space and water heating. Therefore, the two base buildings proposed by Prabatha et al. [13] were employed in this study to represent the different heating energy sources in Canadian single-family detached houses. BB-1 and BB-2 represent houses in which the space and water heating energy demand are catered by electricity and NG, respectively. In addition to the energy supply sources, all other characteristics of BB-1 and BB-2 are similar. Characteristics of the base buildings are summarized in Appendix A.

The retrofit performance and sensitivity analysis were done with reference BB-1 and BB-2. Even though these two representative buildings in Kelowna, BC were selected for demonstration purposes, the proposed framework can handle any number of building archetypes deemed necessary by the decision makers to sufficiently represent a given building cluster or community in any location (i.e., the application of the proposed framework is not limited to Kelowna or the two building archetypes involved or residential building sector). For demonstration purposes, total incentives offered for any retrofit strategy (hence, for a given building) were capped at CAD 10,000. The decision makers can adjust this constraint as applicable to their communities, depending on the budget availability.

Capital cost and embodied emission data of the retrofits are summarized in Appendix B. Space and water heating systems that required source switching from electricity to NG did not show any emissions-saving potential under any of the future scenarios considered. Therefore, those options were omitted from the BB-1 retrofits options list. However, both NG and electric space and hot-water heating upgrades were considered for BB-2. The current energy costs and operational emissions were used as the baseline for the comparison. A summary of the current energy source details of BC is presented in Table 2.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Table 2. Emission factors and price for energy sources [13].

Source	Emission Factor	Energy Price
Electricity	0.0129 $kgCO_2$/kWh	11.62 cents/kWh
Natural Gas	49.58 kg/GJ 0.1784 kg/kWh	7.36 $/GJ 2.65 cents/kWh

The annual energy use of the base buildings is summarized in Table 3.

Table 3. Annual energy use of the base buildings [13].

Building	Electricity	Natural Gas
BB-1	56,767 kWh	-
BB-2	5804 kWh	6015 m^3, 236 GJ, 65,556 kWh

3.1. Operational Uncertainties

The energy use of a building can significantly vary with occupants' practices and operational conditions. Therefore, uncertainties introduced by these factors were modelled, as shown in Table 4.

Table 4. Operational Uncertainties.

Parameter	Lower Bound of the Fuzzy Number	Average User (Likely Value of the Fuzzy Number)	Upper Bound of the Fuzzy Number
Number of adults	avg + 1	Three adults [13]	avg-1
Percentage time inside the house	60%	50% [13]	40%
Appliance, lighting, and other loads	90% of avg.	Base load information is summarized in Appendix C. [13]	110% of avg.
Domestic hot water consumption and temperature	197*l*, 53 °C	247*l*, 55 °C [13]	297*l*, 57 °C
Daytime heating temperature	20 °C	21 °C [13]	22 °C
Nighttime heating temperature	17 °C	18 °C [13]	19 °C
Setback duration	9 h	8 h [13]	7 h

3.2. Environmental Uncertainties

As seen in Equation (5), operational emissions are directly correlated to the emission factors of the energy sources. Therefore, the retrofit evaluation process considered potential variations of the NG and electricity emission factors. BC natural gas providers plan to make the domestic NG supply greener by injecting renewable NG (RNG) into the gas network. RNG has a smaller emission factor (0.2932 $kgCO_{2e}$/GJ) as opposed to the much higher emission factor of conventional NG (49.87 $kgCO_{2e}$/GJ). A major NG provider in BC predicts that RNG could cater to approximately 25–46% percent of the NG demand by 2036 with the technology developments in the biogas sector [10]. Two scenarios were considered assuming a gradual growth of RNG inclusion in the gas network to reach 25% and 46% by 2036. The same predicted NG inclusion growth rate was also assumed to continue from 2036 to 2040.

The average emission factor for the project period was represented using a fuzzy number accounting for alternative energy supply realities aligning with the predictions, as shown in Table 5. The Upper Bound of the emission factors was defined considering that the electricity emissions factor will stay the same while the NG emissions factor reduces due to RNG inclusion in the supply. Under the current conditions, renewable energy sources account for approximately 92% of the BC electricity grid's installed capacity [50]. As of

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

2020, the installed generation capacity of the province is 18,286 MW [51]. According to the literature, the installed capacity is expected to increase at an approximate annual growth of 1% until 2040 [52]. In the Upper Bound (from Table 5), a 500% increment of the electricity emission factor was used to represent a future where the approximate demand growth (20% from current demand) in the next two decades is supplied by NG-based electricity generation stations. Likely Value presents a reality where NG-based generators supply 50% of the excess demand.

Table 5. Fuzzy conditions used to represent emission factors.

	Electricity Emission Factor	NG Emission Factor
Lower Bound	Stays at the present value	Reduces by 28.5% from the present value
Likely Value	Increases by 250% from the present value	Reduces by 15.5% from the present value
Upper Bound	Increases by 500% from the present value	Stays at the present value

These fuzzy numbers were used to represent electricity and NG emission factors.

3.3. Economic Uncertainties

Energy prices of NG and electricity can affect the effectiveness of retrofit performance. Therefore, fuzzy numbers were developed to represent energy prices similar to the emission factors. Electricity price is linked with the grid energy mix and many other factors, including government policies [53,54]. BC's current grid electricity price is 11.62 cents/kWh [13]. The current price was taken as the reference energy price for the study. Electricity price is expected to increase by 8.1% [54] in the coming five years, and it could be approximately represented by an annualized increment of 1.16% each year compared to the previous year. It was predicted to grow by 13.7% from 2013 to 2024 [54], and this prediction can be represented as an annualized value of 1.15%. If an average price hike of 1.155% was assumed for the project period (2020–2040), then the average electricity price is 12.96 cents/kWh. The aforementioned growth predictions are closely falling on each other. Therefore, the anticipated uncertainty is minimal. A variation of $\pm$1% was introduced to the electricity price to account for uncertainties due to price fluctuation.

NG cost in the region considered is 7.89 CAD/GJ [55]. Approximately 5.5 CAD/GJ is charged for delivery, storage, and transport, while the cost of gas is 2.28 CAD/GJ. Over the past decade, gas prices have varied between 2–5 CAD/GJ approximately [56]. Following the great financial recession in 2008–2009, gas prices have hiked up to 10 CAD/GJ. The fuzzy number of the NG price was developed, assuming such price extremities will not be present in the coming two decades, and the NG cost will vary between 2–5 CAD/GJ range with an average of 3.5 CAD/GJ. Charges other than the gas cost were assumed constant in the project time. With these assumptions, the average gas price is 9 CAD/GJ. The Upper and Lower Bounds are 10.5 and 7.5 CAD/GJ, respectively.

4. Results and Discussion

The proposed research methodology was demonstrated through a case study. The detailed results and outcomes of the study are discussed in the following sections.

4.1. Sensitivity Analysis

The results of the sensitivity analysis are discussed below.

4.1.1. Energy Demand Sensitivity to Operational Conditions

PEDC against the operational conditions was observed. It was observed that PEDC variation with the increasing input and output values was symmetric (i.e., reductions in input parameters will create a mirrored pattern of what is seen in Figure 2 in the third and fourth quadrants of the graph). Moreover, two buildings (BB-1 and BB-2) considered in the

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

study indicated similar trends in the sensitivity analysis. Therefore, the results related to BB-1 with increasing operational parameter values are presented in Figure 2 to examine the sensitivity analysis results. Detailed sensitivity analysis results are attached in Appendix D.

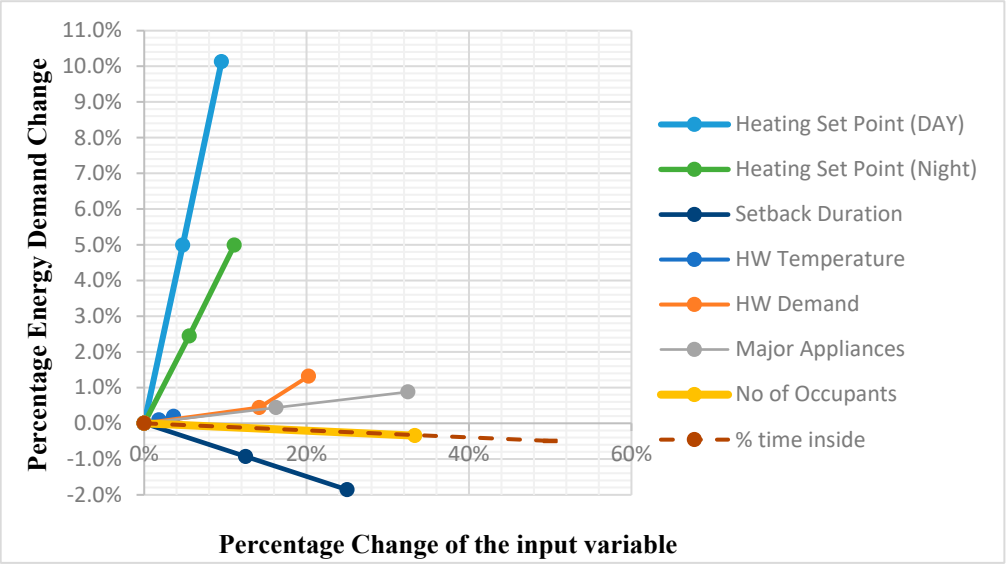

Figure 2. Energy demand sensitivity to operational conditions.

Figure 2 indicates that variations in the parameters related to the heating system, including the heating set points and setback duration, can significantly change the operational energy demand. This indicates the importance of smart controllers for temperature and setback duration control in residential buildings. In addition to smart controllers, occupants can adopt energy-conscious behaviours such as wearing an additional layer of clothing instead of increasing the heating setpoints.

The hot water temperature, HW demand, and major appliance load variations create comparable impacts on the PEDC. Even though these parameters do not create as high an impact as heating system parameters, demand savings achieved by altering these parameters can be easily achieved by adopting less intrusive energy efficiency solutions. (e.g., adopting water-efficient faucets, purchasing energy-efficient appliances when replacing the older ones, and adjusting the average water temperature in day-to-day use).

In general, the energy demand of a house is responsive to the number of occupants and the time spent at home parameters due to changes in energy demand for lighting, hot water, appliances, heating, and cooling. Figure 2 shows that when the number of occupants and time inside the house increase, the energy demand reduces. This energy demand reduction happens due to the energy savings from the space heating system with the increasing passive heat gains from the occupants. This observation is understandable as the heating energy demand dominates the building energy use in most parts of BC and Canada. Importantly, in HOT2000, baseload values do not automatically update with occupancy parameters. Therefore, the observed variation does not include the impact on energy use due to baseload variations resulting from the occupancy patterns. Therefore, baseload parameters must be manually adjusted when altering the number of occupants in HOT2000 models.

4.1.2. Operational Cost and Emission Sensitivity to Source Conditions

A 50% price variation was introduced to energy prices following the scenarios discussed in Section 2.1.2. The results are presented in Figure 3.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

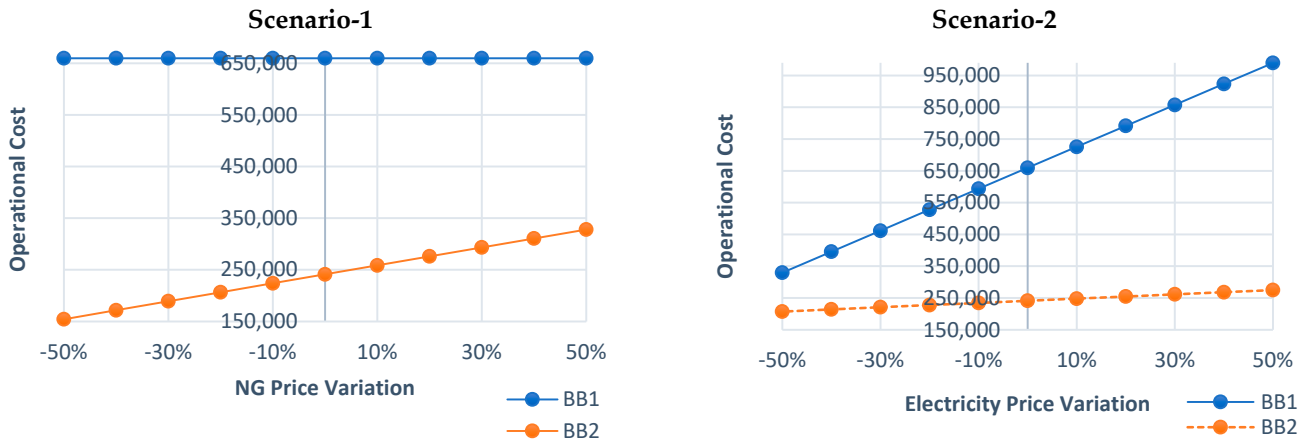

Figure 3. Operational cost vs. energy price variation.

According to Figure 3, it is evident that even after a 50% increment in NG price or a 50% decrement in electricity price, the electrically heated house has a higher operational cost under the current conditions of the two buildings. However, BB-1 is only equipped with electric baseboards for heating. Suppose an electric heat pump was used for heating BB-1. In that case, there is a possibility of operating BB-1 at a lower cost compared to the NG-heated house (BB-2) when the electricity price drops to the lowest levels presented above.

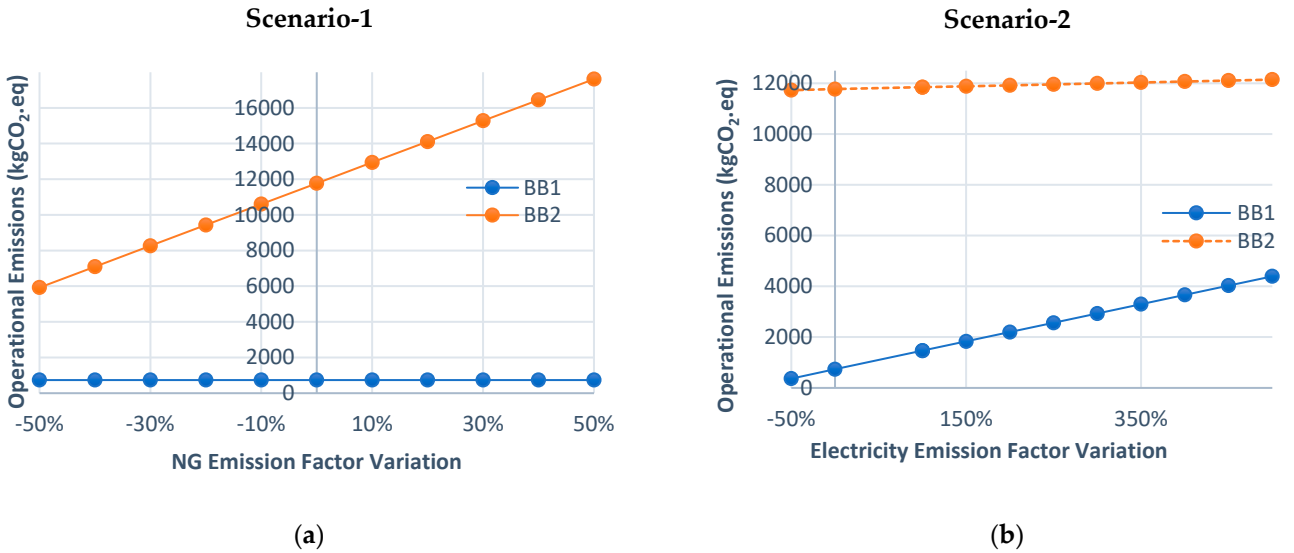
In Figure 4, NG and electricity emission factors were varied following scenarios 1 and 2 from Section 2.1.2. In scenario 1, the NG emission factor was varied by ±50%. BC electricity demand is growing due to numerous factors, including population and industrial growth. On top of that, some government initiatives aggressively motivate the conversion of fossil fuel-based systems (such as building space heating and transportation) to electricity. With this new trend, alternative energy sources such as solar photovoltaic arrays, wind energy, and NG might be integrated into the grid if hydroelectricity becomes insufficient to cater to the provincial demand. However, according to a demand forecast by a major electricity supplier in the province, the total electricity demand growth from 2020 to 2040 is less than 20% [52]. A 500% increment in the electricity emission factor will be observed in an unlikely future scenario where the total provincial energy demand growth (20% from current demand) in the next two decades is supplied by NG-based electricity generation. As renewable energy sources already cater to the majority of the BC electricity supply, the potential for emission factor reduction is minimal. However, a 50% emission factor reduction was considered to study the potential operational savings in a scenario like that. In scenario 2, the electricity emission factor varied from −50% to 500%.

As seen in Figure 4, electrically heated houses (BB-1) produce much lower operational emissions under both scenarios. The operational emissions' performance of the electrically heated house is better even after reducing the emission factor of NG by 50% and increasing the emission factor of electricity to 500% of the current value. It is important to note that the operational performance of an electrically heated house can be further improved by introducing heat pumps instead of the baseboards used in BB-1.

4.2. Retrofit Performance Outcomes

The priority assigned to LCES (W_2) was varied from 0% to 100% (i.e., the weight of LCCS (W_1) was varied from 100% to 0%) to understand the effect of the weights assigned to decision priorities on the percentage occurrence of building component upgrades in the best 100 ranked retrofit strategies. Figure 5 indicates the variation in the percentage inclusion of building component upgrades in top-ranked retrofit strategies vs. the relative importance of LCES. Here, the top-ranked 100 retrofit strategies (combinations) were explored in depth to quantify the number of times a particular retrofit type appeared in the solutions. For example, Figure 5 highlights that the HWU appeared in 80–100% of the solutions under all decision scenarios.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA



(**a**) (**b**)

Figure 4. Operational emissions vs. energy source emission factor variation: (**a**) Scenario-1; (**b**) Scenario-2.

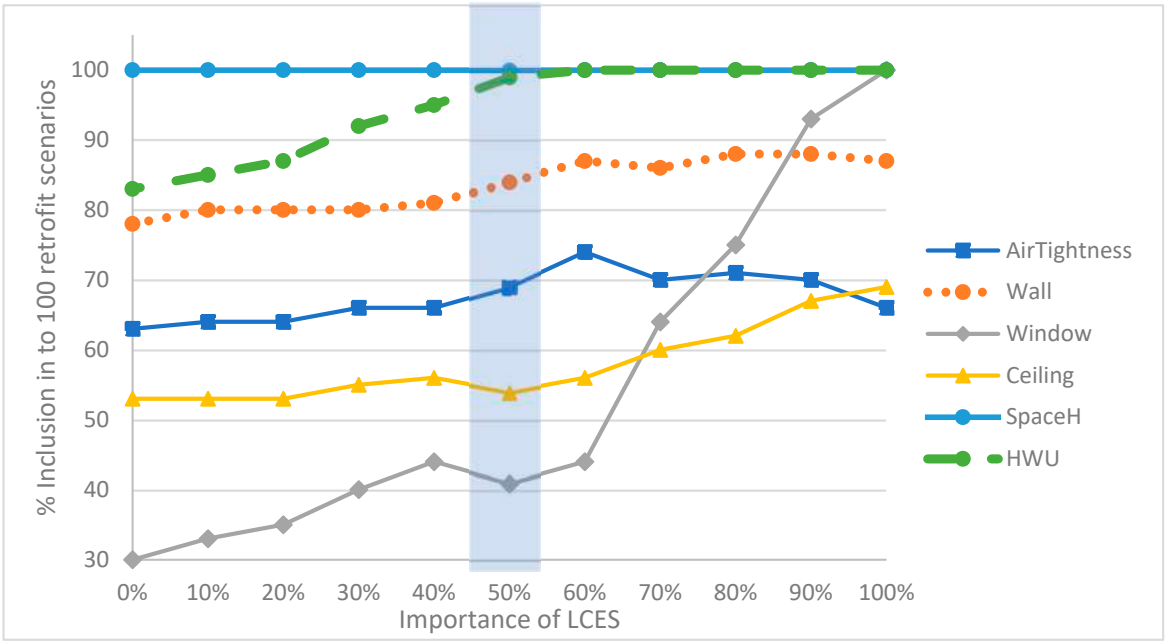


Figure 5. Percentage inclusion of upgrades vs. relative importance of LCES.

When W_2 is below 50%, all the upgrades in the top-ranked 100 strategies were proposed to be applied on BB-1. Similarly, when W_2 is above 50%, all the upgrade scenarios ranked in the top 100 options were proposed to be applied on BB-2. When LCES and LCCS were given equal weights, most upgrade scenarios in the first 100 ranks were proposed for BB-1, while 12% were proposed for BB-2. Notably, this is the only decision scenario (W_2 = 50%) where upgrades for both BB-1 and BB-2 were included in the best 100 options at the same time. The first two observations confirm the BC provincial government's interest in retrofitting and source-switching initiatives focusing on houses heated with NG from an emissions point of view.

From Figure 5, it is evident that space heating upgrades are commonly selected under any weighting scenario. The HWU upgrades closely follow the same trend. However, HWU upgrade percentage inclusion reduces slightly below 85% when the relative importance

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

of LCES is below 50%, yet being the second most used upgrade. Wall upgrades and air tightness are the third and fourth best-performing retrofits, irrespective of the decision priorities. Ceiling upgrades are included 50–70% of the time in the best 100 retrofit strategies, regardless of the decision priority. However, when the relative importance of LCES grows beyond 70%, 80%, and 90% (i.e., LCCS becomes less important), window upgrades become a common inclusion in the top-ranked retrofit strategies compared to ceiling, air tightness, and wall upgrades, respectively. Windows are disadvantaged compared to other retrofits due to the high capital cost. It is important to note that at 100% importance for LCES (i.e., 0% importance for LCCS), windows are included in all of the best 100 retrofit strategies, indicating that window upgrades have a significant emissions reduction potential. A detailed summary of the upgrades included in the best 100 ranked options under varying decision priorities is presented in Appendix E.

4.3. Incentive Performance

Incentive performance was evaluated under varying decision priorities. Only the top-ranked retrofit strategies were considered for incentivizing as the goal of the incentivizing is to promote the best. The incentive amounts applied to individual retrofits vary with the number of retrofit strategies (e.g., 50, 100, 500) shortlisted for incentivizing. The number of strategies incentivized can be decided based on the marginal abatement cost, LCCS, and LCES benchmarks established by the decision makers. For demonstration purposes, the incentive amounts applicable for individual retrofits were determined considering the best 50, 100, and 500 retrofit strategies out of the 2736 retrofit strategies considered. Detailed incentive optimization results are presented in Appendix F.

4.3.1. Optimal Incentive Allocation

In this discussion, the incentive amounts that can be optimally allocated to promote the top 100 retrofit strategies were analyzed for demonstrative purposes. In the top 100 retrofit strategies, when the LCES weight exceeds 50%, all the incentives focus on retrofits applied on BB-2. Similarly, when LCES weight is less than 50%, the incentives are focused on retrofits applied on BB-1. Optimal incentive amounts for each decision priority scenario are presented in Figure 6. The legend contains the capital costs of each retrofit option within brackets.

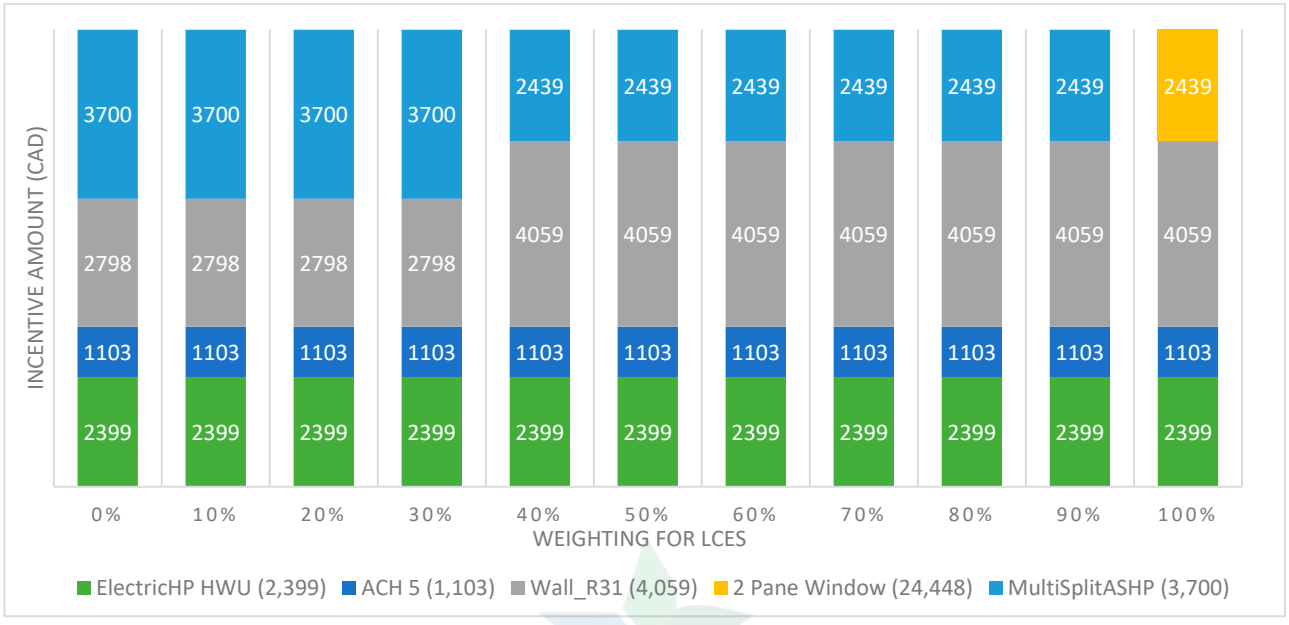

Figure 6. Incentive amount vs. relative importance of LCES to incentivize best 100 retrofit strategies.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

According to Figure 6, the Electric-HP HWU upgrade and airtightness upgrades are incentivized under all decision scenarios, and the incentives are proposed to match the capital cost of the retrofit. Upgrading walls to R-31 (5.459RSI) is the other retrofit proposed to be incentivized under all decision scenarios. Multi-split ASHP is also a retrofit proposed to be incentivized under any decision priority except when the only decision criterion is LCES. When the focus is more biased towards LCCS than LCES, the multi-split ASHP is incentivized to match its capital cost. These are the decision scenarios where the wall upgrade is not incentivized to match its capital cost. If a higher priority is given to LCES, then the proposed incentives cover the entire capital cost of the wall upgrades instead of multi-split ASHP. When 100% focus is on LCES, two-pane windows were incentivized instead of multi-split ASHP. This is understandable as the window upgrades cannot compete with the other retrofits in financial aspects due to their high initial cost.

4.3.2. Incentive Effectiveness

The incentive effectiveness can be evaluated considering the average LCES and LCCS reduction per dollar incentive. The incentive effectiveness variation with the changing weights (representing the variation in the relative importance of the key decision criteria) for the best 100 retrofit strategies is summarized in Figure 7.

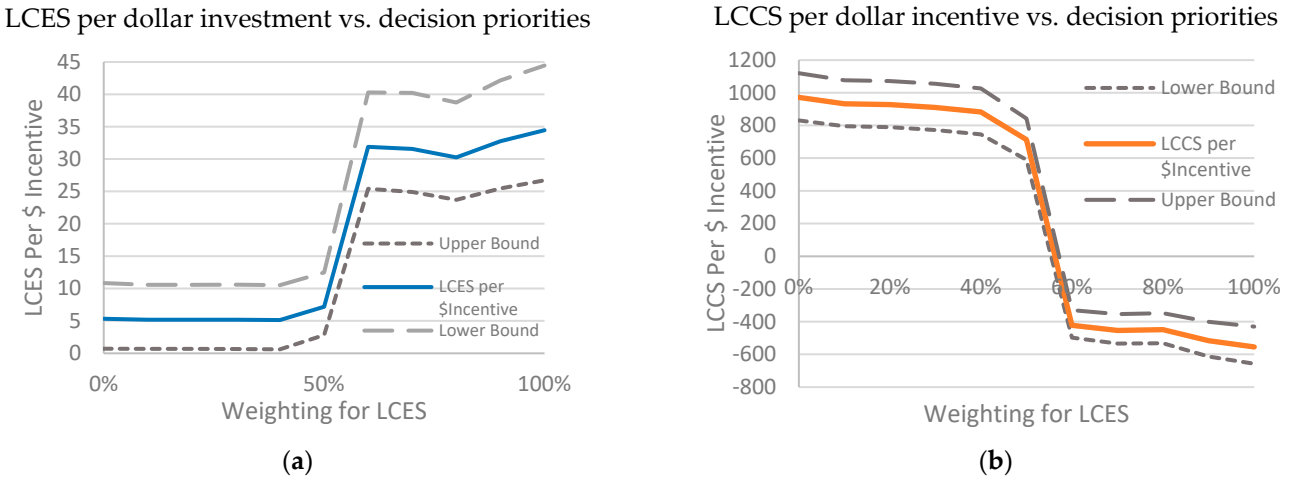

Figure 7. Incentive effectiveness vs. relative importance of LCES: (**a**) LCES per dollar investment vs. decision priorities; (**b**) LCCS per dollar incentive vs. decision priorities.

The solid lines in both Figure 7a,b indicate the average performance that can be expected. The dotted lines indicate the possible range within which the performance can vary due to uncertainties such as emission factors, energy prices, and occupant behaviours. As seen in Figure 7, the decision priorities significantly impact per dollar LCES and LCCS potential of incentives. It is observed that LCES shows a rapid increment, and LCCS experiences a dip when the priority for LCES exceeds 50%. This can be mainly attributed to the characteristics of the base building to which the retrofits were applied. When the LCES priority is above 50%, all the top retrofit strategies are related to BB-2. When LCES priority is less than 50%, all the top retrofit strategies are proposed for the BB-1 house. This observation highlights that more LCES per dollar of incentives can be achieved by retrofitting houses with NG heating, while more LCCS savings can be achieved from the retrofits applied on BB-1.

Retrofitting BB-1 can produce 1-10kgCO_{2e} LCES per dollar incentive. Even though this is not matching the LCES levels of BB-2, this shows a greater potential for community penetration with the LCCS to building owners. If energy-conscious behaviours can be promoted, BB-1 can reach the upper threshold of emissions and cost savings (i.e., energy-conscious behaviour can approximately double the emission savings achieved by retrofitting an electrically heated house compared to energy-intensive occupant behaviours).

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Retrofitting houses heated with NG makes more sense from an emissions-saving point of view because it can generate LCES as high as seven times the savings of a similar building heated with electricity. However, implementing retrofits on BB-2 with the view of emission savings can create life cycle financial losses in the range of CAD 0–25,000 even with the proposed incentives. Therefore, promoting energy retrofits to BB-2 owners is still challenging from an economic point of view.

When determining the financial viability of retrofit projects, capital cost should be considered in addition to the LCC figures, as high capital costs tend to drive away building owners from implementing retrofits. The case study indicates that the average CC of the chosen retrofit strategies notably increases with the increasing priority assigned to LCES, as the focus is mainly on emissions reduction rather than cost. When the importance given to LCCS exceeds 50% (i.e., LCES weight $\leq$ 50%), the average incentive level approximately covers more than 25% of the average CC of the retrofit strategies considered, and all the strategies are recommended for electrically heated houses. If higher LCCS are supplemented with richer incentives, retrofitting electrically heated houses can be easily promoted in the community compared to houses heated with NG.

In summary, it is safe to say that there is a limit to promoting emissions savings solely by overcoming the associated capital cost barriers via incentives. However, low-interest loans can significantly support building owners to overcome capital cost barriers in high capital cost options.

5. Conclusions

This study proposed a framework to find optimum incentive levels for individual energy retrofits to promote the best-performing retrofit strategies (combination of retrofits). The framework considers the life cycle emissions and cost-saving potential in selecting the best retrofit strategies for a given jurisdiction and the optimal incentive levels to promote them under uncertain conditions. The uncertainty-capturing capability of the framework allows the decision makers to identify the strategy, which is robust under future energy supply condition, weather, and macroeconomic changes. Accounting for uncertainties is crucial in climate policy development, given the highly volatile nature of the global economy and climate conditions.

The framework was demonstrated using two case study buildings in Kelowna, BC, with identical characteristics except for the heating energy source (electricity vs. NG). According to the case study, retrofitting the house with electric space and water heating (BB-1) showed greater LCCS potential with relatively lower LCES than retrofitting the house with NG space and water heating (BB-2). On the other hand, any retrofit applied on BB-2 led to higher LCES and lower LCCS compared to BB-1. Despite the high LCES potential of retrofit strategies applied on BB-2, associated net positive LCC (i.e., negative LCCS), particularly with source switching (from NG to electricity) make promoting them in communities challenging even with the proposed incentives. In such situations, other merits of electric retrofits can be leveraged to encourage source switching (e.g., heat pumps can produce cooling for summer while catering to the heating requirements in the winter as opposed to NG-heating counterparts; heat pumps can produce other benefits such as better indoor air quality).

Despite the economic challenges, switching from NG to electricity can significantly reduce the emissions of buildings in BC, which is crucial for meeting provincial emissions reduction targets. However, source switching can potentially increase the utility bills for the building owners and create reliability issues for the heating supply when a majority of the buildings depend on one energy source for heating in a country with extreme winters. With stepwise carbon tax increases, the financial disparity between NG and electric heating is reducing in BC. Even though carbon tax effectively reduces the reluctance for source switching by closing the economic performance gap between the sources, it does not reduce the actual cost of electricity usage for the occupants. Therefore, high energy costs could exacerbate other issues around housing affordability and energy security, which British

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Columbians already experience in the face of a predicted economic recession. Therefore, policy decisions around source switching extend beyond the climate change mitigation discussion. Understanding these challenges, the provincial government supports the community in source switching with general and income-qualified rebate programs with special attention to vulnerable populations.

Without any major physical retrofitting in houses, the combined effect of injecting RNG into the NG supply and adopting energy-conscious behaviour patterns by building occupants over energy-intensive practices can result in LCES over 100,000 $kgCO_{2e}$ and LCCS closer to CAD 20,000 per house heated with NG, over the twenty-year project period considered in the study. The life cycle emissions saving achieved by increasing the RNG fraction in the NG supply and simply adopting energy-conscious behaviour in the NG-heated houses is almost two times the maximum emission savings achieved by any retrofit strategy applied to the house heated with electricity. This highlights the importance of raising community awareness regarding energy-conscious behaviour and the merits of employing performance-based incentives that can also reward energy-conscious behaviours, in addition to asset efficiency, to reduce emissions. Considering the discussed benefits of performance-based incentives and widespread usage of prescriptive incentives in BC, a mix of both approaches can expedite the realization of provincial residential emission reduction targets.

Limitations and Future Work

This paper only considered two base buildings representing Canadian averages for demonstration purposes. Nevertheless, the proposed incentive optimization strategy can comfortably handle multiple building archetypes and designs to cater to city-level planning. A comprehensive building cluster analysis and modelling are recommended for better accuracy in a city-level analysis.

The lack of locally applicable life cycle impact data for BERs, especially for HVAC and hot water systems, was identified as a major gap in the current body of knowledge. The accuracy of the life cycle emissions assessments can be improved with accurate embodied impact data.

The proposed framework can determine the optimal incentive levels to be assigned to individual retrofits to promote the desirable retrofit strategies for a given community, depending on the decision priorities. However, suppose the available budget is limited, and the incentive amount assigned to a given retrofit is not sufficient to change a purchase decision. In that case, the program uptake in the community can be lower. Therefore, the authors suggest conducting stakeholder engagement sessions and surveys to understand the minimum incentive levels needed to motivate the building owners to consider a given retrofit. The survey information can be integrated into the optimization algorithm to avoid assigning insufficient incentive amounts to impact purchase decisions and use those funds to strengthen the incentives for other retrofits that can potentially change the choice of building owners with the increased financial support.

Some energy-efficient and environmentally friendly retrofits (e.g., heat pumps) can be expensive compared to their counterparts. However, these retrofits can produce additional benefits, such as occupant comfort and health, which can be leveraged to promote them in communities. Therefore, the authors recommend the extension of the proposed framework to capture those aspects in future studies.

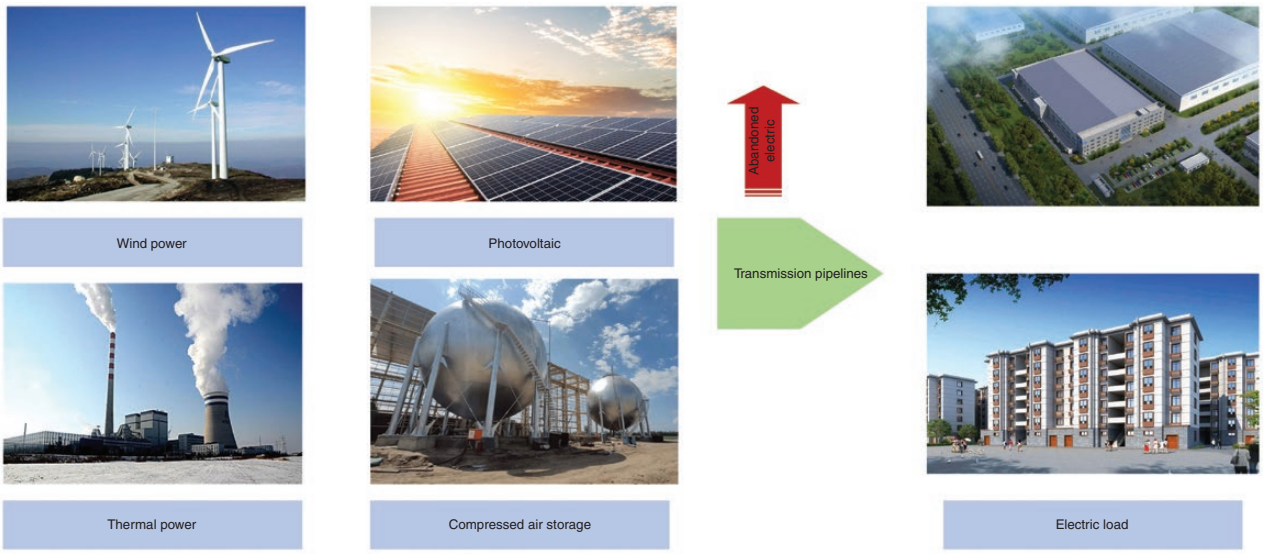
Abstract

China will strive to achieve a 'dual carbon' target: 'carbon peak' by 2030 and 'carbon-neutral' by 2060. In this context, improving the efficiency of renewable energy and reducing the use of thermal power are important ways to achieve the target. Clean, efficient and large-capacity energy-storage technology is the key to improving the utilization rate of renewable energy. First, this paper proposes to use compressed-air energy-storage technology instead of the old energy-storage technology to build an economical and environmentally friendly comprehensive energy park capacity optimization configuration model. Second, this paper uses the newly proposed improved chicken swarm optimization algorithm to solve the model, which is more accurate and faster. Finally, this paper analyzes a comprehensive energy park in north-west China. Through case analysis, it can be seen that the average utilization rate of renewable energy can reach 73.87% through the model proposed in this paper, while the average power-abandonment rate is only 9.32%.

Graphical Abstract



Keywords: renewable energy; compressed-air energy storage; power-abandonment rate; chicken swarm optimization

Introduction

With the rapid development of China's economy, a large amount of fossil energy is consumed, resulting in increased greenhouse gas emissions. According to statistics, China's primary energy consumption accounted for 21.9% of the world's in 2013 and China's carbon dioxide emission ranked first in the world in 2014 [1]. Given this situation, China, as one of the world's major powers, must take immediate action to save energy and reduce emissions. However, how to achieve carbon intensity targets while maintaining economic growth has become an important topic in the field of ecological economy–environment.

To address climate change, the Chinese government has clearly set the 'dual carbon' goal of achieving carbon peak by 2030 and carbon-neutral by 2060, striving to gradually achieve net-zero carbon dioxide emissions. Literature [2] analyzes and summarizes the challenges faced by China in achieving carbon-neutrality

and proposes to improve energy efficiency through technological reform and innovation; develop clean energy; promote energy conservation, emission reduction and energy conversion; and promote low-carbon and zero-carbon economic and social development by using negative emission technologies. China's energy system needs a complete transformation to become carbon-neutral. Literature [3] examined China's decarbonization path and energy transition to carbon-neutrality, and put forward policy suggestions that China should promote renewable energy to replace fossil energy in the electric power field and attach importance to the development of energy-storage facilities.

According to the above suggestions, one of the key measures to achieving the goal of 'dual carbon' is to improve the utilization rate of renewable energy, which is characterized by intermittence and uncertainty. With improvement in the utilization rate of renewable energy, it will bring technical challenges to the security of supply and demand matching of the power system. More efficient and safer storage is needed to smooth out the volatility of a renewable power supply. In order to improve the operation efficiency of the power system and ensure the safety of the power supply, it is urgent to build a batch of large power energy-storage peak-regulating devices. At present, there are mainly pumped hydro-storage power stations and compressed-air storage power stations in the world. Among them, compressed-air energy storage (CAES) is another system that can realize large-capacity and long-duration electrical energy storage. CAES utilizes electricity that is hard to store, such as wind power and solar energy, to generate compressed air. The compressed air with high pressure is stored in gas-storage facilities and can be released as needed to drive turbines for power generation. CAES is second only to pumped storage on a larger scale and is suitable for large power stations. CAES systems can continue to work for hours or even days. Compared with pumped energy storage, CAES has fewer site restrictions. At present, research on CAES mainly includes system optimization [4, 5], process operation [6] and thermal parameter simulation [7–9]. CAES is an energy-storage method that uses electric energy to compress air during the off-peak load of the power grid and release compressed air from high-pressure gas storage for power generation during the peak load of the power grid [10–15].

CAES is not only conducive to reducing carbon dioxide emissions, improving economic performance and increasing environmental protection, but also can restrain the impact of renewable-energy grid connection on the power grid and reduce the use of fossil-fuel-fired thermal energy, so it is conducive to the safe operation of the power grid with a high proportion of renewable energy [16–21].

Reasonable capacity allocation can give full play to the complementary effect of comprehensive energy parks, absorb more renewable energy and reduce the power-abandonment rate [22, 23]. In pluripotent complementary aspects, including scenarios for energy-flexible short-term power, thermal power concrete has good load performance. Literature [24] put forward a renewable-energy optimization method of the minimum life-cycle cost of the system based on a combination of solar photovoltaic (PV) and wind power and biomass to meet existing demand. The biomass power generation is low, so the use range of the integrated energy system is small. Literature [25] put forward the concept of constructing virtual power plants and proposed the application of multiple power-generation equipment and battery energy-storage equipment to form multiple virtual power plants. However, the cost of battery storage is high and the corresponding environmental protection and economics are not as good as CAES. Literature [26] established a unit commitment model for hydropower and thermal power cogeneration to support the safe and economical integration of wind power generation. This model took into account the online power-generation reserve, slope power-generation reserve and transmission capacity reserve to offset the inherent variability and uncertainty of wind power generation. At present, there are few research studies on the capacity configuration of an integrated energy park involving CAES. The above literature regards the utilization rate of renewable energy and power-abandonment rate as important constraint conditions, which will lead to a low utilization rate of renewable energy and a high power-abandonment rate considering the economics. In view of these problems, this paper proposes that CAES is taken as the energy-storage equipment of the comprehensive energy system, and the utilization rate of renewable energy and the power-abandonment rate are taken as constraint conditions during model construction to ensure the consumption level of renewable energy.

In terms of model solving, this paper proposes the application of a novel improved chicken swarm optimization (CSO) [27]. In practical application, the main objective function has strong randomness and it is difficult to determine some problems. The ε-constraint method cannot be used for large-scale problems [28]. Intelligent algorithms solve non-linear and large-scale problems, but they have disadvantages; they are time-consuming and can easily fall into a local optimum state, and there is room for improvement [29, 30]. Literature [27] proposed that the improved CSO has good performance and positively affects local optimization problems. Compared with the genetic algorithm and the particle swarm optimization algorithm, CSO has the advantages of faster convergence speed and higher convergence. Therefore, in this paper, the improved CSO algorithm can avoid falling into the local optimum solution and can solve the problem faster than the general intelligent algorithm.

In this paper, a capacity optimization allocation model aimed at cost minimization is constructed and the CSO algorithm based on the Lévy flight improvement algorithm is applied to solve the model.

The contributions of this paper may be summarized as follows:

(i) This paper proposes to replace an old battery energy storage with CAES, which is safer, more economical and more environmentally friendly.
(ii) In this paper, a capacity optimization allocation model with renewable-energy utilization as the constraint condition and cost minimization as the objective is constructed. It ensures the utilization rate of renewable energy and the economy of power system construction of an integrated energy industrial park.

The remainder of the paper is organized as follows. Section 1 describes the output model of the new integrated energy industrial park, including the output model of renewable energy composed of wind power and photovoltaic power and the CAES system. Section 2 constructs the main capacity optimization allocation model of this paper, which aims at minimizing the cost and constrains the utilization rate of renewable energy to ensure a high proportion of renewable-energy utilization rate. Section 3 describes the CSO algorithm, which is used to solve the model. Compared with the traditional algorithm, the CSO algorithm has simpler calculation steps and faster convergence. In Section 4, a case study is given. Through calculation, the optimization model

Downloaded from https://academic.oup.com/ce/article/6/2/305/6563874 by guest on 24 March 2023

proposed in this paper not only ensures the economy of power construction in the integrated energy industrial park, but also ensures the utilization of a high proportion of renewable energy.

1 Output model

Fig. 1 shows the comprehensive energy park studied in this paper. Renewable energy mainly includes wind power generation, photovoltaic power generation, conventional thermal power and a CAES system for energy storage. There are power transmission channels in the park. On the one hand, it is necessary to ensure sufficient power load on the load side; on the other hand, power abandonment will occur when the electricity generated is redundant. In this paper, the annual cost is minimized and the economic requirements of the comprehensive energy park are met by ensuring a higher utilization rate of renewable energy and a lower power-abandonment rate.

1.1 Renewable energy

A variable-speed constant-frequency wind-turbine generator is widely used at present, and the relationship between the fan output and the wind speed meets the following formula:

$$P_{wt} = \begin{cases} 0, & 0 < v < v_0 \text{ or } v > v_e \\ \frac{p_r \cdot v_0^3}{v_0^3 - v_r^3} + \frac{p_r \cdot v^3}{v_i^3 - v_r^3}, & v_0 \le v < v_r \\ p_r, & v_r \le v < v_e \end{cases} \quad (1)$$

where v_0, v_e and v_r are the cut-in wind speed, cut-out wind speed and rated wind speed, respectively; and p_r is the rated power of the wind-turbine generator. When the wind speed is too high or too low, the output power of the wind-turbine generator is 0.

Photovoltaic power generation is affected by random factors such as the sunshine intensity, sunshine incidence angle and climate environment in the region. Meanwhile, photovoltaic power generation is also affected by differences in photovoltaic cell conversion efficiency and panel area size:

$$R_{pv} = S_{pv} \cdot \eta \cdot r \quad (2)$$

The above formula is the formula for photovoltaic output where R_{pv} is the maximum output power of the photovoltaic panel; η is the conversion efficiency of the photovoltaic panels; r is solar irradiance; and S_{pv} is the total area of the photovoltaic panels.

1.2 Compressed-air storage

This paper takes the non-adiabatic CAES system as the research object, as shown in Fig. 2, which is a schematic diagram of CAES. During off-load periods, the system converts electrical energy into heat and potential energy by compressing air, which can be used to store electrical energy. During peak demand times, the system releases compressed air to generate electricity.

$$S_{CAES}(t) = S_{CAES}(t-1)\left(p_{ch}\eta_{ch} - \frac{p_{dis}}{\eta_{dis}}\right) \cdot \Delta t \quad (3)$$

where $S_{CAES}(t)$ is the electrical quantity of the CAES system at time t; $S_{CAES}(t-1)$ is the electrical quantity of the CAES system at the previous moment; p_{ch} and p_{dis} are the charge and discharge powers of the CAES system, respectively; and η_{ch} and η_{dis} are the charge and discharge efficiencies of the CAES system, respectively.

2 Model

The purpose of using CAES is to improve the utilization rate of renewable energy such as wind power and photovoltaic, reduce the phenomenon of abandoning wind power and light power, and improve the safety and reliability of the power system.

2.1 The objective function

On this basis, it is further necessary to consider the investment and operation cost of wind power, photovoltaic and CAES, and optimize the allocation of wind power, photovoltaic and CAES capacity under the condition of meeting the minimum constraints of wind, light and power abandonment, in order to achieve the goal of maximizing economic benefits and minimizing costs:

$$minC_{total} = C_{wt} + C_{pv} + C_{caes} + C_{ther} \quad (4)$$

$$C_{wt} = Q_{wt} \cdot c_{wt} \cdot f_{wtr} + \mu_{wt} \cdot p_{wt} \cdot T_{wt} \quad (5)$$

$$C_{pv} = Q_{pv} \cdot c_{pv} \cdot f_{pvr} + \mu_{pv} \cdot p_{pv} \cdot T_{pv} \quad (6)$$

$$C_{caes} = Q_{caes} \cdot c_{caes} \cdot f_{caes} + \mu_{caes} \cdot p_{caes} \cdot T_{caes} \quad (7)$$

$$C_{ther} = Q_{ther} \cdot c_{ther} \cdot f_{therr} + \mu_{ther} \cdot p_{ther} \cdot T_{ther} \quad (8)$$

where C_{total}, C_{wt}, C_{pv}, C_{caes} and C_{ther} are the total cost, wind power cost, photovoltaic cost, CAES cost and thermal power cost, respectively;

Q_r is the installed capacity; c_r is the unit cost capacity; f_{r_r} is the depreciation coefficient of the power plant; and μ_r is the operation and maintenance cost coefficient.

2.2 The constraint

In the process of capacity ratio optimization, there are certain constraints on the output power of a wind power generator set, photovoltaic generator set and thermal power generator set as well as the charge and discharge times and discharge depth of the energy-storage system, so as to ensure the power supply reliability of the power system:

$$p_{wt}(t) + p_{pv}(t) + p_{caes}(t) + p_{ther}(t) = L(t) \tag{9}$$

where $p_{wt}(t)$, $p_{pv}(t)$, $p_{caes}(t)$, $p_{ther}(t)$ and $L(t)$ refer to the output of wind power, photovoltaic, CAES, thermal power and load at time t, respectively.

$$Q_{wtmin} < Q_{wt} < Q_{wtmax} \tag{10}$$

$$Q_{pvmin} < Q_{pv} < Q_{pvmax} \tag{11}$$

$$SOC_{min} < SOC(t) < SOC_{max} \tag{12}$$

$$P_{ther\ min} < P_{ther}(t) < P_{ther\ max} \tag{13}$$

$$\gamma_u \leq \frac{p_{wt}(t) + p_{pv}(t)}{L(t)} \tag{14}$$

Equations (10) and (11) constrain the installed power-generation capacity of wind power and photovoltaic power. Equations (12) and (13) constrain the output of the CAES and thermal power at time t. Equation (14) restrains the minimum output value of renewable energy, where γ_u is the minimum utilization rate of renewable energy.

3 CSO based on Lévy flight improvement

The CSO algorithm simulates the hierarchical structure and foraging behaviour of flocks, including roosters, hens and chicks, and can effectively extract the intelligence of flocks to optimize the problem. The CSO algorithm can solve all kinds of numerical problems in the field of scientific research simply and quickly, and has the advantages of fast convergence speed and high convergence efficiency. The behaviour of chickens can be simplified into three aspects:

(i) There are several groups of chickens. Each group consists of a dominant rooster, several hens and chicks.
(ii) How the flock is divided into groups and the identity of the chickens (roosters, hens and chicks) depend on their own adaptations. The few chickens with the best fitness will be considered roosters and each rooster will be the alpha of the group. The chickens with the worst fitness will be designated as chicks. The others should be hens. The hens were randomly chosen for which group to live in. The mother–child relationship between a hen and her chicks is also randomly established.
(iii) The hierarchy, dominance and mother–child relationship within the group remain unchanged. These states are updated every few (G) time steps. Chickens follow their roosters to find food and they may prevent the roosters from eating their own food. The assumption is that chickens will randomly steal good food that others have already found. The chicks are looking for food around their mother (hen). Dominant individuals have the advantage in food competition.

For a rooster, his position is updated as shown in Equations (15) and (16):

$$X_{i,j}^{t+1} = X_{i,j}^{t} * (1 + Randn(0, \sigma^2)) \tag{15}$$

$$\sigma^2 = \begin{cases} 1, & if\ f_i \leq f_k \\ exp\left(\frac{(f_k - f_i)}{|f_i| + \varepsilon}\right), & otherwise,\ k \in [1, N], k \neq i \end{cases} \tag{16}$$

where $Randn(0,\sigma^2)$ is a Gaussian distribution; ε is a constant; k is randomly selected data that meet $k \in [1, N]$, $k \neq i$; and f is the fitness corresponding to x.

The update mode of the hen's position is shown in Equations (17) and (18):

$$X_{i,j}^{t+1} = X_{i,j}^{t} + S1 * Rand * (X_{r1,j}^{t} - X_{i,j}^{t}) + S2 * Rand * (X_{r2,j}^{t} - X_{i,j}^{t}) \tag{17}$$

$$S1 = exp\left(\frac{(f_i - f_{r1})}{(abs(f_i))} + \varepsilon\right) \tag{18}$$

$$S2 = exp(f_{r2} - f_i) \tag{19}$$

where $Rand$ represents a random number evenly distributed among [0,1]; $r1$ is the label of a rooster randomly selected, as the spouse of the i-th hen; $r2$ is the label of a chicken randomly selected; and $r1 \neq r2$. $f_i > f_{r1}$, $f_i > f_{r2}$, so $S2 > 1 > S1$.

The chick's position is updated as shown in Equation (20):

$$X_{i,j}^{t+1} = X_{i,j}^{t} + FL * \left(X_{m,j}^{t} - X_{i,j}^{t}\right) \tag{20}$$

where $X_{m,j}^{t}$ represents the position of the mother of the i-th chicken; FL is a random parameter; and the FL of each chicken will be random in (0,2) value.

The step-size of the Lévy flight is a random process and the calculation method is shown in Equation (21):

Downloaded from https://academic.oup.com/ce/article/6/2/305/6563874 by guest on 24 March 2023

$$s = \frac{\mu}{|\nu|^{\frac{1}{\beta}}} \tag{21}$$

where $0 < \beta \leq 2$, $\nu : N(0,1), \mu : (0, \sigma_\mu^2)$, the variance σ_μ is described as in Equation (22):

$$\sigma_\mu = \left\{ \frac{\Gamma(1+\beta)\sin(\frac{\pi\beta}{2})}{\Gamma\left[\frac{(1+\beta)}{2}\right] \cdot \beta \cdot 2^{\frac{(\beta-1)}{2}}} \right\}^{\frac{1}{\beta}} \tag{22}$$

The position updates of the hen and the chick are added to the optimal individual for learning, as shown in Equations (23) and (24):

$$\begin{aligned} X_{i,j}^{t+1} = {} & X_{i,j}^{t} + S1 * Rand * (X_{r1,j}^{t} - X_{i,j}^{t}) \\ & + S2 * Rand * (X_{r2,j}^{t} - X_{i,j}^{t}) + s1 * (X_{best,j}^{t} - X_{i,j}^{t}) \end{aligned} \tag{23}$$

$$X_{i,j}^{t+1} = X_{i,j}^{t} + s2 * (X_{m,j}^{t} - X_{i,j}^{t}) + s3 * (X_{best,j}^{t} - X_{i,j}^{t}) \tag{24}$$

where $s1$, $s2$ and $s3$ represent the step-sizes of the Lévy flight.

4 Case

Taking a certain area in north-west China as an example, this area plans to build an integrated energy industrial park, in which the rock cave CAES power station, wind engine power station, photovoltaic power station and thermal power station are configured to meet the daily electricity demand of the industrial park. This paper uses the CSO algorithm to solve the model in MATLAB® software.

Based on data from projects in the region, the system efficiency of CAES is 60% and the unit investment is 8500 yuan/kW. The construction period is set to be 1 year and the operation period is 25 years. The initial unit investment cost of thermal power is 4800 yuan/kW. The operation period is 35 years. The initial unit investment cost of the wind power station is 7150 yuan/kW. The operation period is 25 years. The initial unit investment cost of the photovoltaic power station is 3000 yuan/kW and the operation period is 25 years.

The system parameters involved in this paper are shown in Table 1.

After obtaining the above device parameters, the CSO algorithm was used to solve the problem. The relevant parameters of the CSO are set as follows. The population size is 100 and there are 500 iterations. The proportions of roosters, hens, mother hens and chickens are 0.2, 0.6, 0.5 and 0.2, respectively. The calculation process is shown in Fig. 3.

This paper studies and analyzes the electricity consumption of an integrated energy industrial park in 1 year. The following results can be obtained by calculation.

Table 1: The system parameters

Quantity	Unit	Value
Wind-turbine rated power	kW	2000
Turbine cut-in wind speed	m/s	3
Turbine cut-out wind speed	m/s	25
Turbine rated wind speed	m/s	10.5
The efficiency of the wind turbine	%	95
Photovoltaic panel rated power	kW	1000
Area of solar panels	m^2	6965
PV panel conversion efficiency	%	77
CAES system charge/discharge efficiency	%	65

As shown in Table 2, the installed capacities of wind power, photovoltaic power, CAES and thermal power are 9983, 9566, 7849 and 2563 kW, respectively. According to the calculation, the comprehensive energy multi-energy system studied in this paper needs to install six wind turbines of 2 MW, 13 photovoltaic panels of 1 MW and 13 MW of CAES.

As shown in Table 3, during the 1-year operation, the average power-abandonment rate is 9.326%, the average utilization rate of renewable energy is 73.877% and the total cost is 1 6141 200 yuan.

According to the actual situation of the region where the project is located, the electric load of the region is predicted and the load data can be obtained as shown in Fig. 4.

Fig. 5 shows the renewable-energy output diagram of the integrated energy industrial park within a year. It can be seen from the data in the figure that the utilization rate of renewable energy is improved in the capacity allocation optimization proposed in this paper.

Fig. 6 shows the distribution of abandoned electricity in the comprehensive energy industrial zone within a year. It can be seen from the figure that the quantity of abandoned electricity within a year is not stable because the utilization rate of renewable energy is improved, so the stability of the power system is worse than that of the period dominated by thermal power. However, the average power-abandonment rate for a year was 9.326%, i.e. lower than 10%, which is considered acceptable.

By the end of 2020, the electricity consumption of the whole society in north-west China was 789.5 billion kWh, the maximum power load was 115 000 MW and the total installed capacity was 337 577 MW. The proportion of energy types is shown in Fig. 7, where HEP stands for hydro electric power.

As can be seen from Fig. 7, the installed renewable energy in north-west China's power grid accounts for <50% of the total. In practice, the share of output from renewables is even lower. The optimized allocation model proposed in this paper improves the proportion of installed capacity of renewable energy. Meanwhile, through case analysis, it can be seen that the output of renewable energy also exceeds 50%, which significantly improves the utilization rate of renewable energy compared with the current situation in north-west China.

5 Conclusion

CAES technology has a forward-looking strategic significance in the context of the grid connection of high proportion of intermittent renewable energy generation. Under the background of the 'dual carbon' target and the increasing proportion of renewable energy, an energy-storage system with compressed air and a coupling system with renewable energy have a promising future. CAES is safer and more environmentally friendly than older types of energy storage, and is more suitable for the current 'dual carbon' goal. In the study of this paper, the average power-abandonment rate of the integrated energy industrial park within a year is <10%, while the average utilization rate of renewable energy is >70%, which greatly reduces the use of thermal power in the case of the CAES system. From the aspect of model construction, the capacity allocation optimization model is constructed with the goal of minimizing cost, which ensures the economy and security of the system.

Bibliometric Analysis of the Use of Biodiesel Production from Essential Oils as Biofuels

Mehmet Ali Biberci

Department of Mechanical Engineering, University of Cankiri Karatekin, 18000 Cankiri, Turkey; m.alibiberci@karatekin.edu.tr

Abstract: Second-generation biodiesel, which is produced from essential oil plants, has important advantages, including a high yield of biofuels and the potential to reduce greenhouse gas emissions. The goal of this research was to examine the profile of original and review articles on biodiesel production from essential oils using bibliometric analysis. The search strategy identified 186 relevant and available peer-reviewed publications from 1981 to 2023, which were downloaded from the Web of Science (WoS) database. The retrieved documents were analyzed using VOSviewer. China was the predominant country publishing those documents, followed by the United States, India, Australia, and France. The keyword cluster analysis indicated the presence of 10 main research topics: diesel, fuel, and engine performance; extraction of lipids from microalgae; biofuel production from essential oils; green chemistry; the pyrolysis process; bioethanol production from renewable raw materials; obtaining biodiesel from essential oils; essential oil extraction; obtaining biofuels; and supercritical fluid extraction for fuels. The top three authors were Rahman, S. M. A., Cantrell, C. L., and Zheljazkov, V.D. The results showed that study topics such as different biodiesel raw material sources, biodiesel conversion technology, and the performance and emission characteristics of second-generation biodiesel are gaining popularity, with the goal to achieve a sustainable and clean environment.

Keywords: bibliometric analysis; biofuel and biodiesel; emission characteristics; engine performance; essential oil biodiesel; clean and renewable energy; sustainability; environmentally friendly; second-generation biodiesel

1. Introduction

Essential oils are concentrated plant extracts containing the aromatic compounds of the plant from which they are derived [1–3]. Essential oils are typically extracted from the flowers, leaves, stems, and roots of plants [4–6]. The extraction process involves steaming or pressing the plant matter to release the essential oil [7–10]. Essential oils can be obtained from plants such as lavender, mint, thyme, sage, and eucalyptus, which are popular medicinal plants [11–13]. These oils are used both in aromatherapy applications [1,14] and in the fight against disease-causing agents in plants [5,15–17]. In addition, biodiesel can be obtained from essential oils [18,19]. Biodiesel can be obtained using biotechnological methods [20,21], the transesterification method, and from solid wastes left after obtaining essential oil from plants [22] via the pyrolysis method.

Biodiesel is a promising alternative to conventional diesel fuel that has the potential to reduce emissions and dependence on fossil fuels [23]. Biodiesel produced from materials such as household food waste, poultry farming waste, and waste tires are classified as first-generation biodiesel fuels [24]. A first-generation biodiesel can achieve good results, as can a second-generation biodiesel [25]. However, the biodiesel production process from first-generation sources is more laborious and complex than that from second-generation sources [26]. The large amount of biomass waste remaining after essential oil production represents an important biodiesel production source [27]. Hence, it has gained increasing

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

attention. Essential oil is derived from plants and has properties that make it a promising feedstock for producing biodiesel [28,29]. It is used to operate diesel engines in vehicles by mixing biodiesel obtained from essential oils with diesel fuel [30,31]. A large portion of carbon monoxide emissions originate from vehicle emissions using fossil fuels [32,33], while a more environmentally friendly, renewable, and cleaner fuel is obtained with the fuel mixture created by adding biodiesel obtained from essential oils to diesel oil [34]. Thus, pollutant emissions released to the environment as a result of fuel combustion are reduced [35,36]. Reducing pollutant emissions also has a positive effect in negating global warming [37–39]. In recent years, there has been increasing interest in the performance and emission characteristics of diesel engines operated by biodiesel produced from essential oil [40,41]. Bibliometric analysis, which employs mathematical, statistical, and other measurement techniques, is useful for revealing the academic strength of a research finding and the possibility of citation/co-citation models [42]. Bibliometric analysis aims to provide a comprehensive overview of the research trends and developments in a field [43–46]. In this study, the goal of bibliometric analysis was to review the literature on the use of essential oils and volatile plant oils as biofuels for compression ignition engines and provide a comprehensive summary of the research in this area as it stands today.

The main objectives of this bibliometric analysis [42,47] were as follows:

1. To perform a thorough analysis of the literature regarding the use of biodiesel production from essential oils to power compression ignition engines.
2. To analyze the research trends and publishing patterns in the field, including the number of publications, authors, countries, and journals.
3. To identify the key topics and research gaps in the field and make suggestions for future investigations.

2. Materials and Methods

2.1. Data Collection

Clarivate Analytics Web of Science (WoS) is a comprehensive academic database that provides access to high-quality research from various scientific fields, including the natural sciences, social sciences, engineering, and humanities [48,49]. The database is widely used by researchers, scholars, and students to find and cite relevant research articles, conference proceedings, and other scholarly materials [50]. One of the notable features of Web of Science is its citation index, which tracks the number of times an article has been cited by other publications. This allows researchers to identify the most influential and impactful research in a particular field and track the progression of ideas over time. In addition, Web of Science includes a variety of search tools and filters to help users find the most relevant and up-to-date research [48,51]. Users can search by keyword, author, publication, or citation and narrow their results by date range, subject area, and other criteria [52,53]. The WoS Core Collection database (1981–present) (last data download 4 February 2023) was utilized to find research publications on the topic of essential oils. Accordingly, 48,537 documents were found that contain the words “essential oil” OR “volatile oil”. To narrow down the findings, the search was restricted to publications with the following keyword query:

Topic: (“biodiesel fuel” OR “engine emission” OR “diesel fuel” OR “pyrolysis” OR “biodiesel” OR “biofuel” OR “diesel”)

Then, 186 articles from the WoS Core Collection were examined, and the findings were further filtered by document type (article or review). There were no language restrictions. Total records and cited references from the analyzed papers were downloaded and imported into VOSviewer (version 1.6.18, 2022, Leiden University, Leiden, The Netherlands) for further citation analysis [54].

2.2. Bibliometric Analysis and Clustering

WoS data were visualized (network and overlay) using the software VOSviewer to determine co-occurrence and clusters of related articles, country, organization, and author

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

collaboration (co-authorship), as well as clusters of interrelated research topics (text data). VOSviewer was utilized to illustrate the international collaboration among the authors, organizations, and nations, as well as trends in research across all keywords [55]. Items are displayed in the figures of this paper by a label and a circle. The weight (relative importance) of an item is indicated by the size of the circle. According to the program's calculations, the colors in the chain representation reflected arrays of related components. The strength of the relationships was represented by the distance between the items [56].

3. Results and Discussion

3.1. Time Trend Analysis, Publication Type, and Language

Increasing population growth, industrialization, and welfare have resulted in an increase in the use of fossil fuels, which has led to an increase in greenhouse gas emissions and climate change. Its adverse effects have been linked to increased floods, droughts, forest fires, and glacier melting, among other natural disasters. At the Paris Climate Conference (2015), which was held during the Conference of the Parties (COP21), an agreement was signed to limit global warming to below 2 °C. Achieving this objective will necessitate severe emission reductions to stabilize the concentration of greenhouse gases in the atmosphere. The substitution of fossil fuels with biofuels derived from plant biomass has the potential to drastically decrease emissions of greenhouse gases [57–60]. For that purpose, biofuels are receiving increasing research attention. In this study, five document types were discovered, under which there were 186 publications researching crops containing essential oils in the production of biodiesel, which is an important biofuel type. The types of documents and languages of the publications are shown in Table 1.

Table 1. Document types and languages of the publications on Web of Science concerning biodiesel production from essential oil.

Rank	Document Type	Records	% of 186	Language	Records	% of 186
1	Article	164	88.172	English	184	98.925
2	Review Article	22	11.828	Chinese	1	0.538
3	Book Chapters	7	3.763	Turkish	1	0.538
4	Early Access	5	2.688			
5	Proceeding Paper	3	1.613			

Among these document types, the most common were 164 articles (88.17%) and 22 reviews (11.83%), followed by 7 book chapters (3.76%), 5 early-access articles (2.69%), and 3 proceedings articles (0.89%). The majority of the documentation is written in English (98.93%), with small amounts in Chinese and Turkish (1.08%). Figure 1 illustrates the increase in the quantity of publications and citations related to the topic. Since the data were retrieved on 4 February, it is not surprising that there are few publications and citations in 2023.

3.2. Categories and Research Areas of Web of Science

In the science edition of WoS, there are sixteen subject categories and sixteen research areas pertaining to the influence of biodiesel production from essential oil (Table 2). The first eight WoS categories are Energy Fuels (33; 17.742%), Chemical Engineering (27; 14.516%), Food Science Technology (21; 11.290%), Analytical Chemistry (20; 10.753%), Environmental Sciences (20; 10.753%), Multidisciplinary Chemistry (19; 10.215%), Applied Chemistry (14; 7.527%), and Agronomy (11; 5.914%). The first eight research areas are Chemistry (60; 32.258%), Engineering (42; 22.581%), Energy Fuels (33; 17.742%), Environmental Sciences/Ecology (24; 12.903%), Food Science Technology (21; 11.290%), Agriculture (18; 9.677%), Biochemistry/Molecular Biology (18; 9.677%), and Science Technology Other Topics (16; 8.602%). The WoS allows for the classification of journals and publications into two or more categories, demonstrating the multidisciplinary character of this subject

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

area [61,62]. The WoS also maps publications to WoS classes, which are more specialized than fields [63,64].

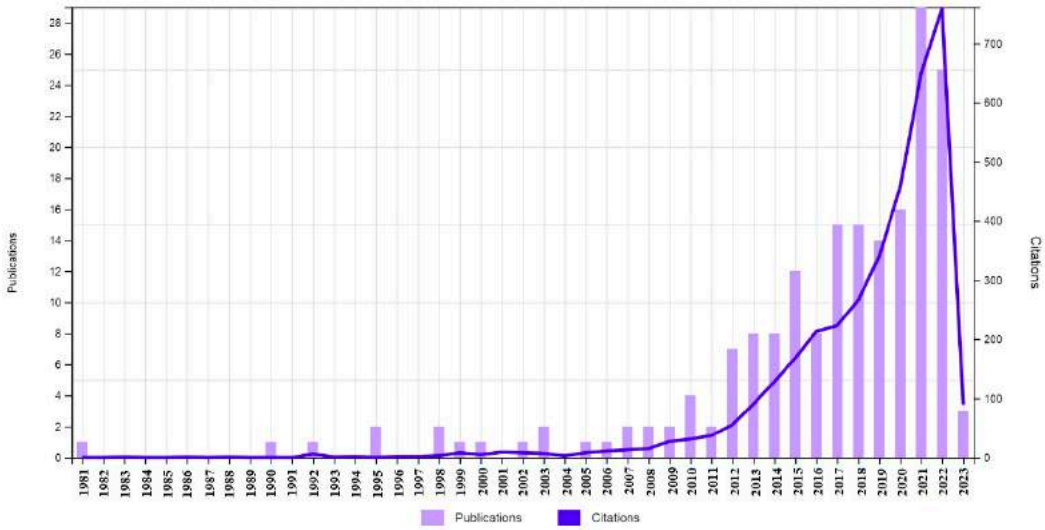

Figure 1. Annual growth of publications and their total citations per year on biodiesel production from essential oil (1981–2023).

Table 2. Web of Science (WoS) categories and research areas concerning biodiesel production from essential oil.

Ratio refers to the percentage out of 186. TP = total publications.

3.3. Core Journals

According to JCR 2021 data (released in 2022), research on the influence of biodiesel production from essential oil is featured in 25 journals across all categories of WoS. The leading 20 base journals are listed in Table 3. The leading 5, leading 10, leading 15, leading

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

20, and leading 25 journals published 13.97%, 21.50%, 26.88%, 32.25%, and 37.09% of the articles, respectively. The most effective journal was *Industrial Crops and Products* with eight articles (4.301%), followed by *Fuel* (7%; 3.763%), *Journal of Analytical and Applied Pyrolysis* (4%; 2.151%), *Journal of Chromatography A* (4%; 2.151), and *Energy Fuels* (3%; 1.613%). Each of these journals published more than three articles. There were 11 journals from Q1 (quartile), 10 journals from Q2, 3 journals from Q3, and 1 journal from Q4 among the top 25 journals (Table 3). It is crucial that the publications appear in a journal with a high impact factor (IF). Citation analysis is not a measure of scientific excellence, but a reflection of its importance [65–67].

Table 3. The top 25 journals on Web of Science for research on biodiesel production from essential oil.

Rank	Journal	TP	Ratio	IF 2021	IF 5-yr	QC
1	*Industrial Crops and Products*	8	4.301	6.449	6.508	Q1

25	*AAPG Bulletin*	1	0.538	3.863	4.470	Q2

Ratio refers to the percentage out of 186. IF = impact factor; QC = quartile in the category; TP = total publications. Data are from the 2021 edition of *Journal Citation Reports*.

3.4. Author Co-Authorship Analysis

Internationally collaborative articles were accompanied by interinstitutional collaborative publications, single-country articles, and single-author articles, which had the maximum visibility and scholarly impact on average [68,69]. According to the publication data, 932 authors produced the 186 works. There were 932 authors who had at least one publication. Nevertheless, just 35 authors were interconnected. Figure 2 displays the WoS authorship network for the study of the effects of essential oils on biodiesel production. The circle sizes show the number of records. Authors who belong to the same cluster have studied the same subject and collaborated closely.

Table 4 includes information on citations, average citations, organizations, and nations for the authors of studies between 1981 and 2023 addressing the impact of adding essential oils to biodiesel production. The leading 20 writers who have produced more than nine articles are included in Table 4, along with their total citations, average citations, organizations, and countries. After correcting for different spellings of author names, the leading five authors were Rahman, S. M. A., Cantrell, C. L., Zheljazkov, V.D., Astatkie, T., and Brown, R. J.; each published more than 2 articles. The top nine authors with the most citations per article were Rahman, S. M. A., Dowell, A., Davin, Laurence B., Cantrell, C. L.,

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Zheljazkov, V. D., Kaloustian, J., Brown, R. J., Nabi, Md. N., Ristovski, Z. D., Islam, M. A. Their average citation per article was over 53.22. Among the top 20 authors, there were six from Australia, four from the United States, four from Hungary, three from Spain, and one each from Canada, Denmark, and France.

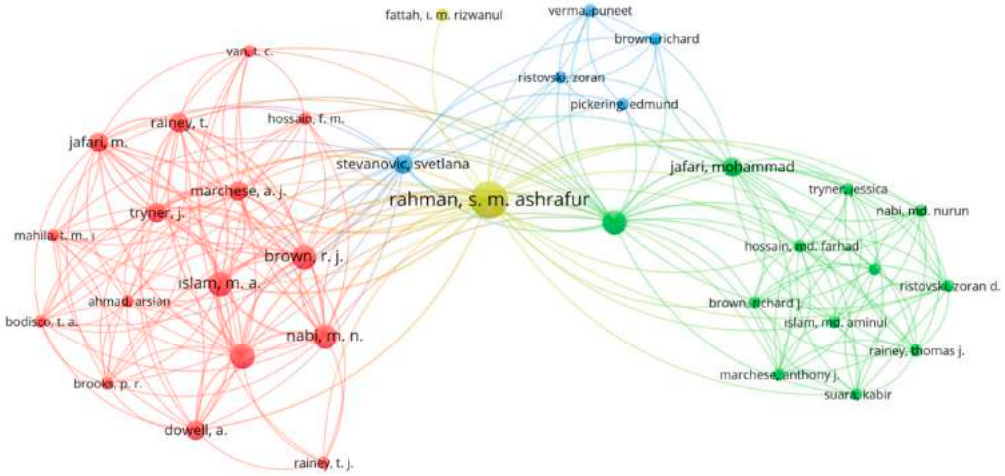

Figure 2. Web of Science network visualization map of authors of studies on biodiesel production from essential oil.

Table 4. Top 20 most prolific authors who published articles in the field of biodiesel production from essential oil on Web of Science.

Rank	Author	Articles	Citations	Organization	Country
1	Rahman, S. M. Ashrafur	6	91	Queensland University of Technology	Australia

3.5. Country/Region Co-Authorship Analysis

There were 54 countries or areas that contributed to this study's 186 papers. The top 14 nations or locations where more than two articles originated are listed in Table 5. The top five article-producing nations were China, the United States, India, Australia, and France. China, France, Malaysia, Canada, and the United States produced the most citations per paper. An international country co-authorship network map was developed using VOSviewer software. The threshold has been set to 1. A total of 53 nations/regions fulfilled the criteria, and 38 nations /regions were interlinked (Figure 3).

Table 5. Top 14 countries/regions publishing articles on Web of Science in the field of biodiesel production from essential oil.

Rank	Country/Region	Records	Cluster	Total Link Strength	Citations
1	China	27	4	5	485
2	United States	23	10	23	332
3	India	23	5	6	258
4	Australia	15	8	17	243
5	France	10	3	4	419
6	Canada	8	5	7	358
7	Egypt	7	5	7	107
8	Malaysia	7	2	2	408
9	Saudi Arabia	5	5	9	38
10	Taiwan	4	1	1	69
11	Greece	3	1	1	75
12	Pakistan	3	3	3	5
13	Republic of Korea	3	5	6	24
14	Austria	2	8	0	34

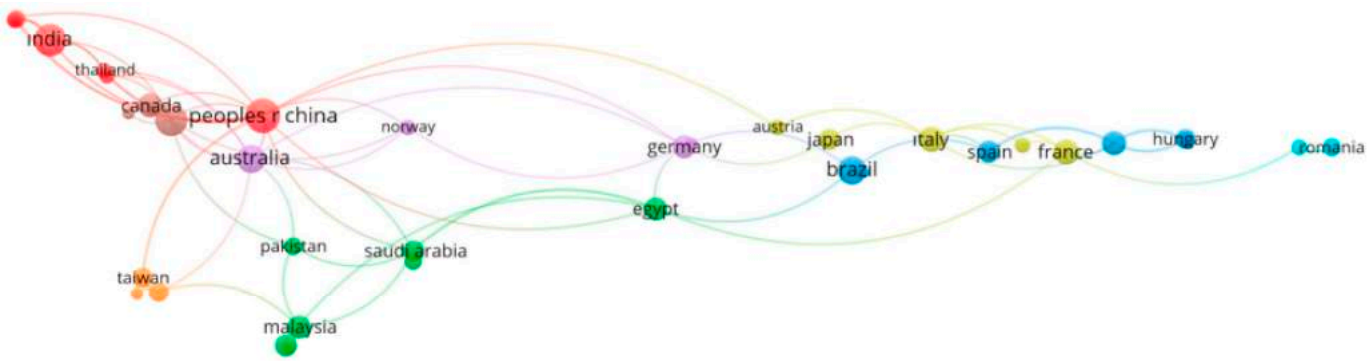

Figure 3. The country co-authorship network of research on biodiesel production from essential oil with 38 nodes and 8 clusters.

The VOSviewer software classified these 38 countries into eight distinct color groupings. The size of a circle symbolizes each record, while the range between nations reflects the power of their relationships. The different color ranges and groups were established in accordance with the countries. India, the United States, China, Germany, Australia, and Brazil had the six largest circles (Figure 3). The initial cluster included seven countries and regions (red color): Bangladesh, India, Mexico, China, Republic of Korea, Thailand, and Vietnam. The second cluster included seven countries/regions (green): Egypt, Greece, Iran, Malaysia, Nigeria, Pakistan, and Saudi Arabia. The third cluster included six countries (blue): Brazil, England, Hungary, Scotland, Spain, and Venezuela. The fourth cluster consisted of five countries and regions (yellow): Austria, Czech Republic, France, Italy, and Japan. The fifth cluster consisted of four countries (violet): Australia, Germany, Israel, and Norway. The sixth cluster consisted of three countries (light blue): Belgium, Estonia, and Romania. The seventh cluster consisted of three countries (orange): Indonesia, Netherlands,

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

and Taiwan. The eighth cluster consisted of three countries (brown): Canada, Sweden, and the United States. China demonstrated increased studies and collaboration in the field of biodiesel production from essential oil. It appears that increasing cooperation results in more sophisticated scientific research output. Hence, geographic location is a significant aspect that influences international cooperation. The increasing number of international exchanges has facilitated scholarly contacts [70–72].

3.6. Organization Co-Authorship Analysis

According to the publication data, 365 organizations produced a total of 186 works. The examination of organization co-authorship indicated the level of communication across institutions as well as the prominent institutions in this field [73–75]. The 365 organizations satisfied the lowest threshold of one; however, 22 organizations were linked to one another (Figure 4). The VOSviewer program color-coded those 22 institutions into four distinct clusters. Localization plays a big role in how partnerships and joint ventures are formed [76,77].

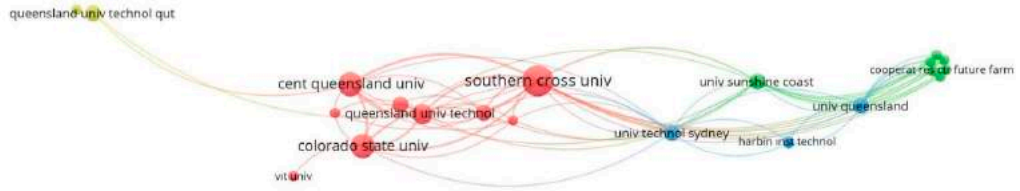

Figure 4. The organization co-authorship network of Web of Science research on biodiesel production from essential oil.

3.7. Co-Occurrence Analysis for All Keywords

There were only 75 keywords out of the 846 in total that met the threshold more than twice. The largest collection of linked items, which included 69 items in total, was divided into 10 major clusters (Figure 5).

The first cluster (red) highlighted diesel, fuel, and engine performance. It consisted of 11 keywords: fuel, fuel properties, diesel, emissions, combustion, combustion characteristics, compression ignition engine, engine performance, terpenoids, and particulate matter.

The second cluster (green) focused on solvents such as limonene, which are used to extract lipids from microalgae. The keywords were ranked as follows: microalgae, limonene, menthol, terpenes, carvacrol, viscosity, activation energy, kinetics, thermal analysis, and response surface methodology.

The third cluster (blue) focused on biofuel production from essential oils. It included keywords such as biofuels, bioproducts, biorefinery, bioactive compounds, crude glycerol, analytical pyrolysis, mass spectrometry, and sustainability.

The fourth cluster (yellow) focused on green chemistry. The keywords included green chemistry, cellulose, holocellulose, lignin, wood, drying, chemical analysis, and ionic liquids.

The fifth cluster (violet) focused on the pyrolysis process and the anti-inflammatory, antioxidant, and antimicrobial activities of pyroligneous acid from *Rosmarinus officinalis*. It included keywords such as pyrolysis, anti-inflammatory, antioxidant activity, antimicrobial activity, GC-MS, pyroligneous acid, and *Rosmarinus officinalis*.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

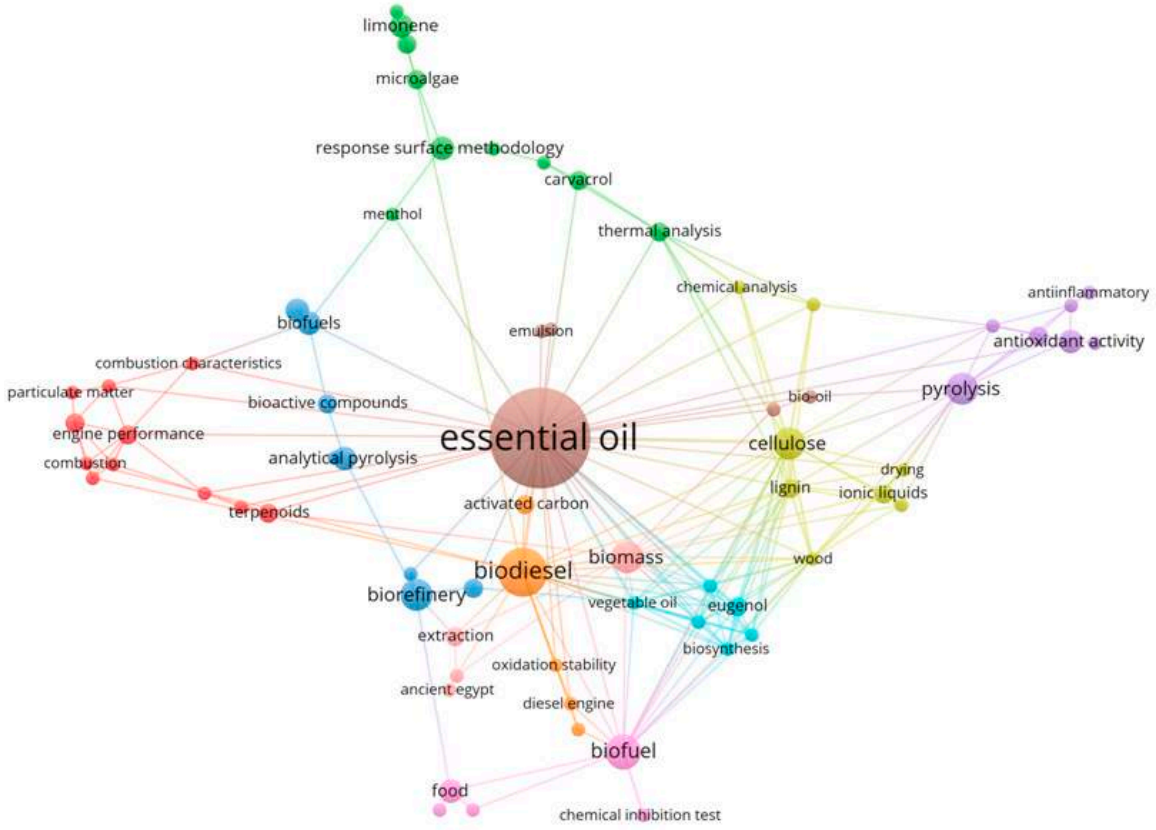

Figure 5. VOSviewer co-occurrence network visualization mapping the most frequent keywords (minimum of two occurrences) in Web of Science research on biodiesel production from essential oil.

The sixth cluster (light blue) focused on bioethanol production from renewable raw materials. The keywords included bioethanol, biosynthesis, eugenol, metabolic engineering, switchgrass, and vegetable oil.

The seventh group (orange) concerned obtaining biodiesel from essential oils. It included keywords such as activated carbon, biodiesel diesel, engine, lemon, essential oil, and oxidation stability.

The eighth group (brown) focused on essential oil extraction. The keywords included bio-oil, emulsion, essential oil, oxidative stability, and pretreatment.

The ninth group focused on obtaining biofuels. It included keywords such as biofuels, chemical inhibition testing, cosmetics, food, and supercritical fluid extraction.

The tenth group focuses on supercritical fluid extraction for fuels. The keywords included ancient Egypt, biomass, extraction, and oxidation.

Figure 6, illustrated by VOSviewer, shows co-occurrence overlay mapping of the most common keywords (a least two occurrences) for Web of Science research on biodiesel production from essential oil. In recent years, it can be seen that some keywords (green-yellow) have been used frequently. These words are: essential oil, biofuel, biodiesel, combustion performance, and microalgae.

4. Conclusions

In this study, 186 WoS papers (articles and reviews) on biodiesel production from essential oils were analyzed. The majority of these papers were written in English (98.93%) and were published by 932 authors from 54 countries/territories and 365 organizations. These papers were published in diverse categories of the WoS Core Collection. The five leading base journals were as follows: *Industrial Crops and Products*; *Fuel*; *Journal of Analytical and Applied Pyrolysis*; *Journal of Chromatography A*; and *Energy Fuels*. The top five article-producing nations were China, the United States, India, Australia, and France. The top five organizations were Queensland University of Technology, Southern Cross University, Central Queensland University, Colorado State University, and UDICE-French Research Universities. The top five authors were Rahman, S. M. A., Cantrell, C. L., Zheljazkov, V. D., Astatkie, T., and Brown, R. J. The keywords from research on biodiesel production from essential oil were divided into ten clusters with distinct research subjects. Cluster interpretation can only be offered exploratorily and is always subjective. Other experts may identify more patterns. In addition to relying on vocabulary chosen by the authors, which may be idiosyncratic, such research is also limited by its reliance on nomenclature. On the other hand, this could be considered a strength since the authors are adept at choosing their terms. They may alter throughout time, which is detectable through visualizations. So, such a study can serve as a resource for researchers. It provides useful information on the current condition of a scientific topic or discipline and predicts potential future advances. The analysis and visualizations shown here provide explorative data about the state of a particular scholarly area/discipline at the present time and suggest potential directions for future research.

Funding: This research received no external funding.

Data Availability Statement: The data presented in this study are available on request from the author.

Conflicts of Interest: The author declares no conflict of interest.

Abstract: This paper concerns the development and analysis of multigeneration systems based on hybrid sources such as biomass and wind. Industry requires different types of sources to provide several outputs, so the goal of this research was to fulfill the industrial requirement with optimization. The multigeneration cycle supplies enough power to satiate energy demands, i.e., power, cooling, hydrogen, air conditioning, freshwater, hot water, and heating. For this, the multigeneration cycle was modeled in the Engineering Equation Solver (EES) and Simulink to obtain optimized results for the industry. Energy and exergy for the multigeneration cycle were determined to assess the performance of the cycle and to investigate the optimized results for the overall system. This study shows that for configuration selection and design, different thermodynamic, economic, and environmental aspects should be considered. Based on the results, the selection of the best location for this multigeneration system was made. Power output from the wind turbine was around 7 MW and from biogas 0.6 MW. The overall exergy efficiency of the multigeneration system was found to be 0.1401.

1. Introduction

Energy is an important part of national development and with the advancement of time, it is becoming a more important requirement. People are now looking for many new ways to increase energy production, and with fossil fuels decreasing day by day, renewable energy is becoming a better option going forward. Being the only means of clean, green, and infinite energy, renewable energy mainly has solar, wind, biomass, geothermal, and hydro as the main sources [1]. A multigeneration energy system is used to utilize more than three sources. A multigeneration energy system provides higher efficiency than the combined equal and separate units. When a multigeneration system uses renewable energy, it combines clean and green energy with higher efficiency. In addition, it also supplies different needs of the public unit such as the neighborhood. Using an energy-based multigeneration system, it has been analyzed that exergy efficiency varies from 55% to 65% depending on the amount of cogeneration used. Murat Ozturk et al. [2] showed that, through the integration of various systems, multigeneration increases energy and exergy efficiencies. Furthermore, it has been determined that, due to renewable energy-based multigeneration, the fuel price decreases, as well as harmful pollutant emissions, compared to conventional systems [3].

The objectives of this paper include first proposing and assessing a new integrated multigeneration system using biomass and wind energy with energy and exergy analyses,

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

including the determination of overall energy and exergy efficiencies of the multigeneration system and its subsystems; and second carrying out a parametric study to determine the effects of various parameters on the overall energy and exergy efficiencies of the multigeneration system and its subsystems. Challenges faced in this research and study include the difficulty of scheduling and modeling the sources; wind, and biomass in this case. Wind energy is not constant throughout the year. It changes with the temperature and season. However, we can use the average wind speed for analysis. In addition, for biomass, the waste disposal can vary from day to day, but through observation, average waste disposal can be found to be used as a reference for calculation.

Renewable energy can be obtained from the biological remains of the living. It is known as biomass, and it can be a great way to get the most out of waste. All living things present on Earth are comprised of biomass. It can either be converted into other forms such as biofuels or it can be used directly [4]. Biomass is used currently for heating, electricity, and cooling [5]. To obtain large-scale utilization, biomass is directly burned using the combustion process of coal, which is considered the most common method of conversion [6]. There are other methods more efficiently feasible than the combustion process for power generation, which include thermochemical conversion technologies such as gasification and pyrolysis. Economically these technologies are not viable for large-scale utilization, or they lack maturity and reliability [7].

A 2-kW biomass-fired micro-scale CHP system was studied by Liu et al. [8] where they used the organic Rankine cycle with three organic working fluids. Efficiency variation was also assessed by them through a parametric study of the CHP system with selected design parameters. Using biomass as a supplementary fuel, Gnanapragasam et al. [9] studied the optimum conditions for a natural gas combined cycle power generation system. In addition, biomass was also used to increase the temperature of flue gases in a supplementary firing unit. Al-Sulaiman et al. [10] reported energy and exergy analyses of a biomass trigeneration system using an organic Rankine cycle. They also performed a comprehensive parametric study of the system and concluded that there is a significant improvement when trigeneration is used in place of only electrical generation.

A biomass-based integrated comprehensive system with hydrogen production was proposed by Safari and Dincer [11] and production rates for power hydrogen (0.347 kg/h), freshwater (0.94 kg/s), and hot water (1.82 kg/s) were 1102 K W/h. Ahmadi et al. [1], developed an integrated bio-mass multi-generation system and concluded that when the system is multi-generating, the potential for CO_2 emission reduction is extensive. Khalid et al. [12], integrated solar and biomass in the multi-generation system, Moradi et al. [13], considered bio-mass gasification only, and Paakkonen and Joronen [14], restudied the feasibility of a biomass-integrated combined heat and power system. Studies in [12–14], revealed that biomass and biogas are highly feasible for comprehensive and multi-generation systems with maximum energy and exergy efficiency of 72.5% and 30.44% and can be derived from environmental wastes such as chicken manure [15,16], maize silage [17], rice husk [18], etc. Sevinchan et al. [19], developed a multi-generation system powered by maize silage and chicken manure. Rice husk was hybridized with solar energy to power another multi-generation system developed in the literature [20]. The ammonia and hydrogen productions by their system [20] were 79 g/s and 20 g/s. Solar and wind are also considered the most commonly used RE sources of power, co-generation, and multi-generation. Ozlu and Dincer [21], analyzed a multi-generation system based on solar and wind energy and reported the overall energy and exergy efficiencies of the systems to be 43% and 65%.

The wind is one of the most abundant renewable energy sources used nowadays. The wind energy can be extracted by a wind energy conversion system (WECS), which is composed of a wind turbine, electric generator, power electronic converter, and the corresponding control system. Wind energy at different wind velocities has to be converted to electric power at the given grid frequency. To choose other components of the wind energy conversion system (WECS), the speed control strategy should be known. Wind turbine configurations are based on different categories, i.e., horizontal and vertical axes,

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

number of blades, and power rating. This paper used a wind turbine of a horizontal-axis type, having three blades and a power output of 0.56 MW [21]. Extended energy, exergy, and economic analyses of a wind turbine were presented in another study and the maximum exergy efficiency was 10.8%. The exergy analysis of a CHP system integrated with wind turbines was presented by Mohammadi et al. [22], and the operating parameters of a hybrid wind–hydrogen system were analyzed energetically and exegetically by Fakehi et al. [23].

Integration of a wind generation system and electrical system development are associated with both benefits and costs. Compromise has been made either in cost or benefit. For example, wind generation required more investment than that of conventional gas or coal plants. Whereas the energy generation from wind saves fuel consumption hence reducing the cost of system operation.

There are some issues related to the integration of wind power into a system. Although the energy produced by a large conventional plant may be displaced by that of wind generation, concerns over system operation costs are focused on whether wind generation will be able to replace the capacity and flexibility of conventional generation plants. Moreover, another important factor is the location of these new sources in assessing the impacts on the transmission and distribution network infrastructure. Wind turbines generally cannot provide a range of system support services (e.g., voltage and frequency regulation) that are provided by thermal and hydro plants.

Wind cannot be considered the sole power generator. It is necessary to retain a portion of conventional plants for backup or to ensure security, especially under conditions of high demand and low wind. This concludes that wind power is variable and not easy to predict, various forms of additional reserves will need to be introduced to maintain a constant balance between supply and demand. So, a conventional generation system cannot be displaced by a wind generation system.

All these studies conclude that a wind energy integrated system is feasible and enhances the performance of the system. The main challenge in this comprehensive system is that most research has been presented on the steady-state condition which gives no insight into the performance of the system while the thermodynamic analysis of wind and biomass for a comprehensive energy system has also been limited. So, the gap can be bridged by developing a novelty for this system. The system will be analyzed in steady-state and time-based conditions and assessing the system by using the Engineering Equation Solver (EES) computer program and Simulink.

2. Materials and Methods

2.1. Developing a Schematic Diagram

For this study, a multigeneration cycle had to be designed to provide power, cooling, heating, freshwater, hydrogen gas, desalinated water, and conditioned air as an output. Multigeneration had to be powered using biogas generated from cow manure as well as wind turbine power. The main aim of this study was to develop a model of the multigeneration cycle using the EES and Simulink for thermodynamic analysis. Finally, the model developed had to be tuned to obtain a steady state for the cycles of the multigeneration system.

Figure 1 shows the system which utilizes wind as a primary source and biomass as a secondary source. The system produces power, cooling, heating, fresh water, hydrogen, hot water, and conditioned air as its output. The components used in this system include generator, compressor, condenser, pump, turbine, expansion valve, electrolyser, evaporator, boiler, heat exchanger, desalination plant, water treatment plant, heat pump, air-conditioning, and refrigeration cycles. Schematic is labelled with total of 31 different states points for which the working fluid or substance for which pressure, temperature, internal energy, enthalpy and entropy had to be determined. All these components work in a flow system to produce the desired output. The schematic of this system is illustrated in Figure 1.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

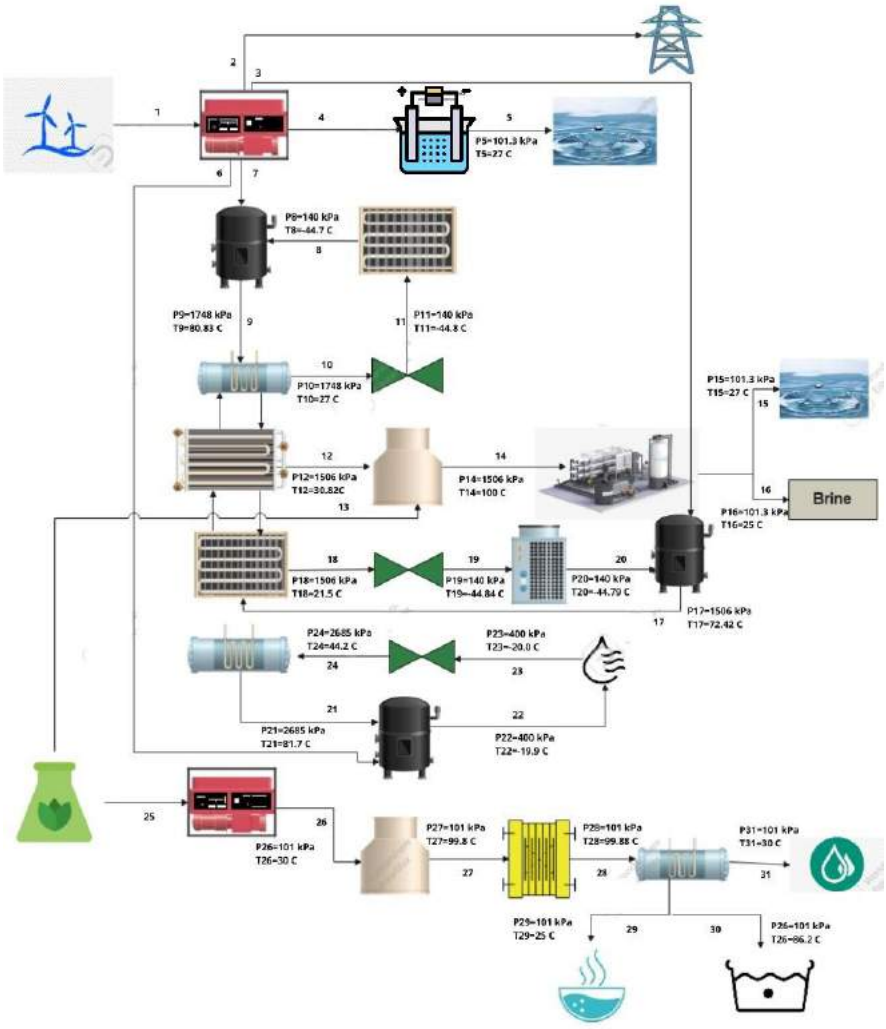

Figure 1. Schematic diagram.

The atmospheric conditions are 28 °C and 101 KPa. Wind velocity is 8 m/s having a power of 1.293×10^6 used to drive the wind turbine that ultimately drives the generator. The wind turbine gives a power output of 1.033×10^7 and this power output is used to produce electricity only. The electrolysis process is performed by using heat from the generator to produce H_2 and O_2. The remaining heat of the generator is used to drive the vapor compression cycle. The working fluid used in the vapor compression cycle is R410, the compressor operates at 80.83 °C, the condenser operates at 27 °C, expansion valve, and the evaporator operates at −44.84 °C. The vapor compression cycle gives cooling as an output. The heat released by the condenser is absorbed by the heat exchanger. The heat exchanger provides water with the heat to initially increase its temperature to 30 °C. The heat exchangers used for this multigeneration system are parallel flow heat exchangers. This heat is utilized by the boiler. The boiler obtains two sources of heat, one from the heat exchanger and the other from biomass. The desalination plant utilizes the steam of the boiler to give fresh water and brine. Thermal desalination is performed using the boiler. Both the boiler and condenser operate at an atmospheric pressure of 101.325 KPa. Water enters the boiler at around 30 °C and leaves as steam. It is then condensed to around room temperature. The temperatures of fresh water and brine are 27 °C and 25 °C.

The heat released by the condenser of the air conditioning cycle is absorbed by the evaporator. The operating temperature of the evaporator is 21.5 °C. The evaporator is also connected to the compressor. Then, the expansion valve opens and the heat pump produces heat. The heat pump then provides the output heat that is used for heating. The

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

compressor of the air-conditioning cycle obtains heat from the wind turbine generator. The air conditioning cycle provides the conditioned air that is used for space heating.

Biomass is used as a fuel for the generator to produce power. The operating condition of the generator is 30 °C. This power is used by the boiler to produce steam. The system heat exchanger absorbs heat from the boiler and gives that heat to the condenser. The condenser obtains cold water from one of its inlets and water leaves as hot water from one of the outlets. After the condensation of steam, treated water is obtained from the system. Treated and hot water are obtained at temperatures of 30 °C and 25 °C respectively. Above all the processes work in rhythm to produce the desired output.

For this multigeneration cycle, several parameters were required. Most of the parameters required were operating intensive properties for the cycle or constraints for the power generation such as wind and biogas. Table 1 shows the parameters required to analyze the whole multigeneration cycle.

Table 1. Parametric table of multigeneration system.

Parameter Value of Multigeneration System	
Wind turbine	
Velocity of the air (V)	8 m/s [24]
Density of the air (p)	1.20 kg/m^3 [24]
Electrical losses	1%
Electricity transmission losses	1.25%
Mechanical losses	3%
Wake losses	5%
Biogas production	
Waste disposal of cow manure per day	20 kg [25]
Volatile solid cow manure per day	1.42 kg [25]
Yield factor	5.5 [25]
Electrolysis	
Voltage for electrolysis (V)	2 V
Energy of hydrogen gas at r.t.p	116648 kJ/k [26]
Energy of oxygen gas at r.t.p	24.68 kJ /kg [26]
Faraday's constant	96485
Vapor compression cycle	
Ambient temperature (To)	25 °C
Compressor isentropic efficiency (n)	0.85
Refrigeration cycle low pressure side (Prc)	140 kPa [27]
Heat pump low pressure side (Php)	140 kPa [27]
Air conditioner low pressure side (Pac)	400 kPa
Refrigerant used for vapor compression	R410a
Mass flow rate of refrigeration cycle (mrc)	14 kg/s
Mass flow rate of the heat pump (mhp)	15 kg/s
Mass flow rate of the air conditioner (mac)	19 kg/s

2.2. Developing Input Source/Components/Process for the Multigeneration Cycle

In the air condition cycle, as shown in Figure 2, analysis was carried out based on the application of the first-order transfer function on different mass values with pressure ranging from 0.2 MPa to 1 MPa. Using the thermostat, the mass flow was controlled by integrating the thermostat between the condenser outlet and the evaporator inlet. The mass flow rate was calculated by using Qin and thus it could be determined how much mass flow rate could be allowed for the conditioning of air.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

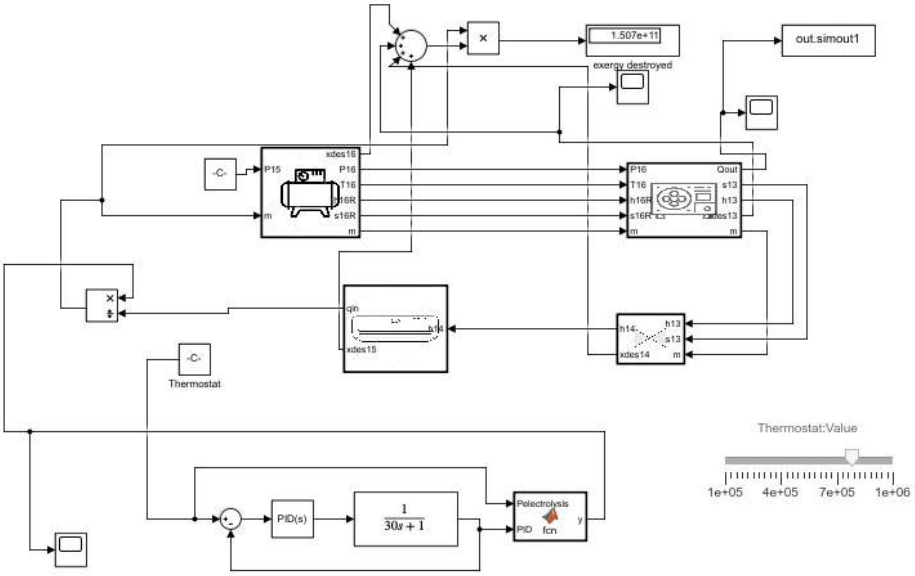

Figure 2. Airconditioning cycle Simulink model.

In the refrigeration process, as shown in Figure 3, the same was conducted based on the application of the first-order transfer function on different mass values with pressure ranging from 0.14 MPa to 0.8 MPa. Using the thermostat, the mass flow was controlled by integrating the thermostat between the condenser outlet and the evaporator inlet. The same method was applied to find the mass flow rate which is by calculation of the Qin of the evaporator and then controlling the mass flow of the refrigerant to obtain the desired cooling.

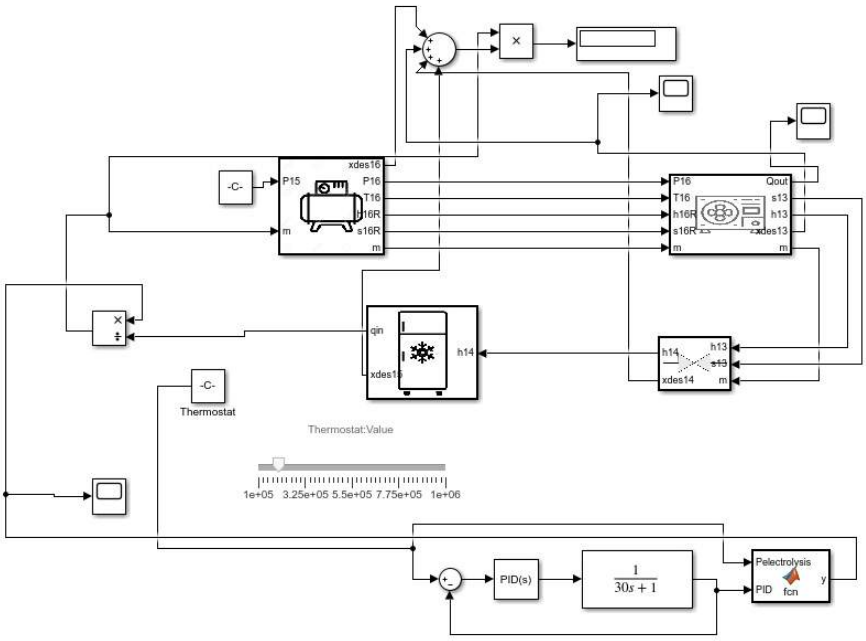

Figure 3. Refrigeration cycle Simulink model.

Almost the same method was applied to the heat pump as shown in Figure 4. Coolprop library was used, and the first order transfer function performed on different mass values: pressure ranges from 0.14 MPa and 0.8 Mpa in the heat pumping also. A thermostat was integrated between the condenser and evaporator, but the only difference observed here is

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

that the useful heat is at the condenser. This heat is used to determine the mass and then it can be varied by changing the mass flow.

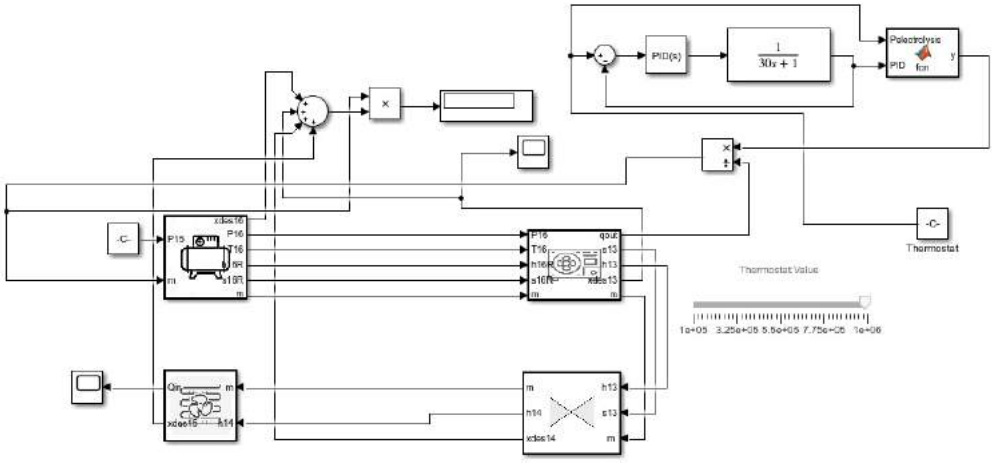

Figure 4. Heat pump Simulink model.

Electrolysis requires the second-order transfer function because it depends on two variables which are the battery response and the hydrogen production rate as shown in Figure 5. When the power is supplied, electrolysis provides the current based on the given power. This current then determines the amount of oxygen and hydrogen produced. So, the production can be varied depending on the two variables that are changed to obtain the best output.

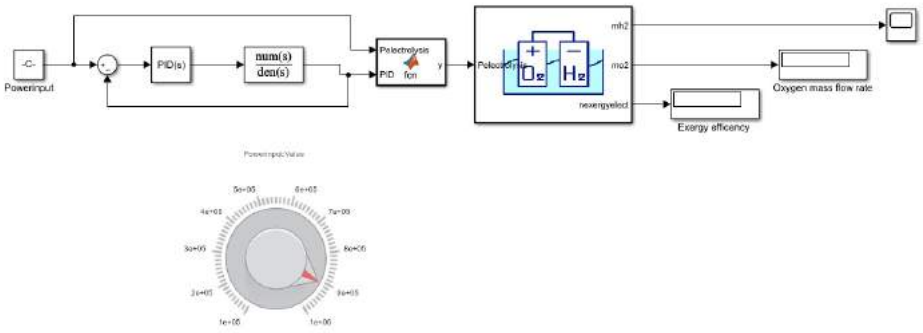

Figure 5. Electrolysis Simulink model.

As in Figure 6 the desalination system is based on the third-order transfer function because it has three different processes which are boiling, condensation, and storage. Output is the treated water against the given power; the water is first boiled which releases brine and steam and then the water vapor is condensed and stored in the collector.

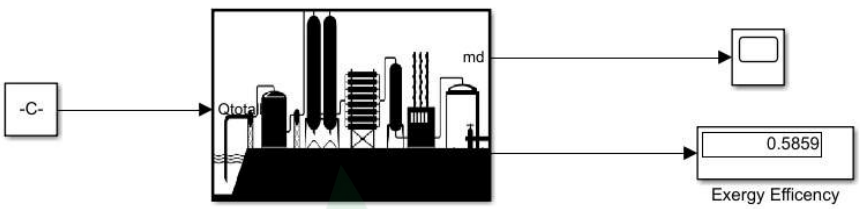

Figure 6. Desalination Simulink model.

As in Figure 7 for the multigeneration system, two renewable energy systems were used, namely wind and biogas. The Betz law and kinetic energy conversion to electrical

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

energy were used to determine total power generation for wind. Biogas energy production was modeled using the estimated power which could be generated from cow manure in a single day. Since the system does not contain major variables which vary with respect to time, for multigeneration sources modeling a zero-order system was assumed.

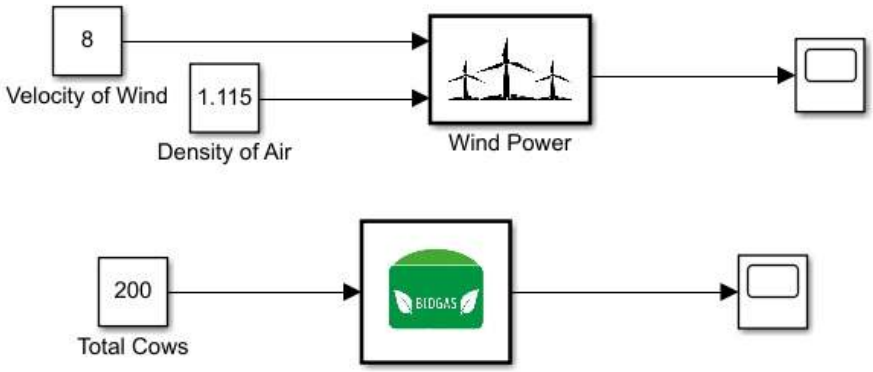

Figure 7. Power generation Simulink model.

As in Figure 8 the hot water system is modeled with respect to time. The mass flow rate cannot be assumed to be zero if the mass flow rate is assumed to approximate zero or the slightest change of heat will result in temperature gain which is greater than zero which results in negative exergy destruction. Exergy destruction can never be negative so modeling steady-state response will result in unreasonable results.

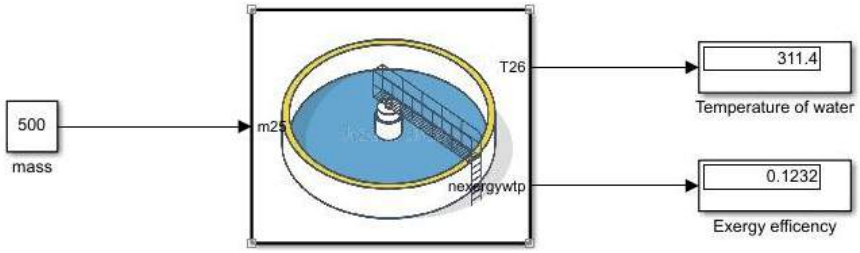

Figure 8. Water treatment Simulink model.

2.3. Approach to Analysis

Exergy can be found by determining the entropy generated between each component of the gas turbine. Exergy destroyed X_{des} is found by multiplying the entropy generated with the outside temperature and exergy destruction can be determined. Where Q_H is heat gained, Q_L is heat released, T_H and T_L are the temperatures at the hot and cold source respectively from initial i to final state f as in Equations (1)–(3)

$$\dot{X}_{dest,\,i-f} = T_0 \dot{S}_{gen,\,i-f} = T_0[\dot{m}\left(s_f - s_i\right) + \frac{\dot{Q}_H}{T_H}] \tag{1}$$

$$\dot{X}_{dest,\,i-f} = T_0 \dot{S}_{gen,\,i-f} = T_0[\dot{m}\left(s_f - s_i\right) + \frac{\dot{Q}_L}{T_L}] \tag{2}$$

$$\dot{X}_{dest,\,i-f} = T_0 \dot{S}_{gen,\,i-f} = \dot{m} T_0\left(s_f - s_i\right) \tag{3}$$

Exergetic efficiency can be found using Equation (4)

$$\eta_{\mathrm{II},des} = \frac{\dot{X}_{\dot{Q}_L}}{\dot{W}_{in}} = \frac{\dot{W}_{min,\,in}}{\dot{W}_{in}} = 1 - \frac{\dot{X}_{dest,total}}{\dot{W}_{in}} \tag{4}$$

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Pelec showed the power transferred to carry out electrolysis as shown in Equation (5) where the current is produced. For the electrolysis, hydrogen and oxygen were produced by consuming the power generated by the generator. Where the amount of the current produced, *fo* is faraday's constant. The equations used for the mass flow rate production of the hydrogen mh_2 and oxygen mo_2 gas are as follows:

$$P_{elec} = I_{cur} \cdot V_i \tag{5}$$

$$mh_2 = \frac{JA_i}{2F} \cdot 0.002 \tag{6}$$

$$mo_2 = \frac{JA_i}{4F} \cdot 0.032 \tag{7}$$

P_{wind} is the maximum expected power generated from the wind turbine in Equation (8) while u is the collective efficiency of the wind turbine. Multiplying P_{wind} with the collective efficiency and Bentz's efficiency P_{output} is determined in Equation (10) which is the actual power consumed.

$$P_{wind} = 0.5\rho v^3 A \tag{8}$$

$$u = (1 - km)(1 - ke)(1 - kt)(1 - kt)C_p \tag{9}$$

$$P_{output} = n_{turb} \cdot u \cdot P_{wind} \tag{10}$$

Applying the approach for energy calculation for small-scale biogas production Equations (11)–(16) are used to determine the estimated amount of energy that could be extracted from the cow's manure [25].

$$T_{waste\ disposal} = totalcows \cdot Wastedisposal \tag{11}$$

$$Total_{volatile\ solid} = Volatile_{solid\ cow} \cdot totalcows \tag{12}$$

$$Conc_{vol\ solid} = \frac{Total_{volatile\ solid}}{Digestor_{vol}} \tag{13}$$

$$S = \frac{Total_{volatile\ solid}}{Volume} \tag{14}$$

$$G = Yieldfactor \cdot S \cdot \frac{Digestor_{vol}}{1000} \tag{15}$$

$$Energy_{prod,days} = 22.08 \cdot G \tag{16}$$

According to the first law of thermodynamics energy balance, the equation has to be applied as in Equation (17). Ein represents the energy input while E_{out} represents the energy output:

$$E_{in} = E_{out} \tag{17}$$

Equations (18) and (19) represent the coefficient of performance for the refrigeration cycle and heat pump cycle:

$$COP_{ref} = \frac{Q_L}{Q_H - Q_L} \tag{18}$$

$$COP_{hp} = \frac{Q_H}{Q_L - Q_H} \tag{19}$$

3. Results

After conducting a literature review, and assuming parameters for the energy sources to power the multigeneration cycle; the multigeneration cycle was designed. It was powered by two sources wind and biogas. This cycle can produce hydrogen, provides desalinated water, treated water, and hot water for residential areas, while operating the

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

refrigerators, air conditioner, and heat pump. The vapor compression cycle is used to operate the refrigeration cycle, air conditioning, and heat pump cycle. Single stage desalination is performed using a boiler operated by biogas energy, another boiler that receives heat input from the biogas is used to treat water and supply hot water to residential areas. Electrolysis produces hydrogen and oxygen gas which can be used for treating metals, processing food, refinement of petroleum, and as fuel.

Figure 9 shows the relationship between the velocity of air and wind power in the wind cycle using the blue line. With increasing velocity of air, the wind power also increases. For an increase in velocity of air from 4 m/s to 8 m/s the wind power increases from 0 W to 11 MW. The relation can be observed as power increases at an increasing rate since the power output is proportional to the cube of velocity. Most of the power generated from the wind turbine is consumed in electrolysis at around 70%. The remainder is used to power the air conditioning cycle, refrigeration cycle, and heat pump cycle.

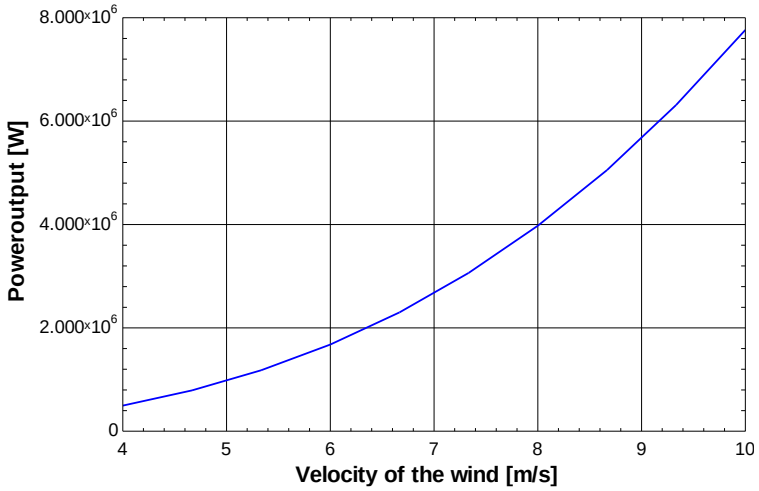

Figure 9. Effect of the velocity of air on wind power.

Figure 10 shows the relationship between the number of cows on a farm and biogas heat generation using the blue line. On increasing the number of cows on the farm, biogas heat generation also increases. For an increase in the number of cows from 50 to 300 the biogas heat generation increase from 0.1 MW to 0.7 MW. Biogas is used to provide heat input to boilers at the single-stage desalination and water treatment plant.

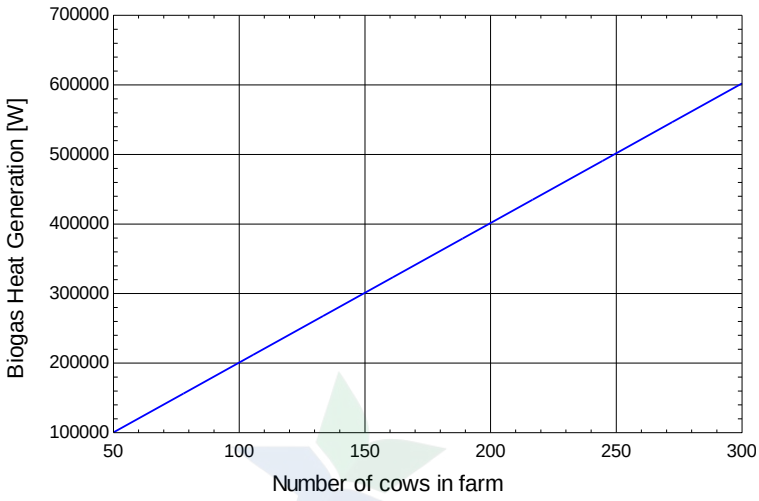

Figure 10. Effect of number of cows on biogas heat generation.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Figure 11 shows the relationship between the velocity of the air and the exergetic efficiency of the air-conditioning cycle, heat pump, refrigeration cycle, and overall exergetic efficiency. It is seen that on increasing the velocity of the air that the exergetic efficiency of the air-conditioning cycle, heat pump, and refrigeration cycle decreases, whereas the overall exergy remains the same. For an increase in the velocity of air from 6 m/s to 8 m/s, the exergetic efficiency varies between 0 to 1.

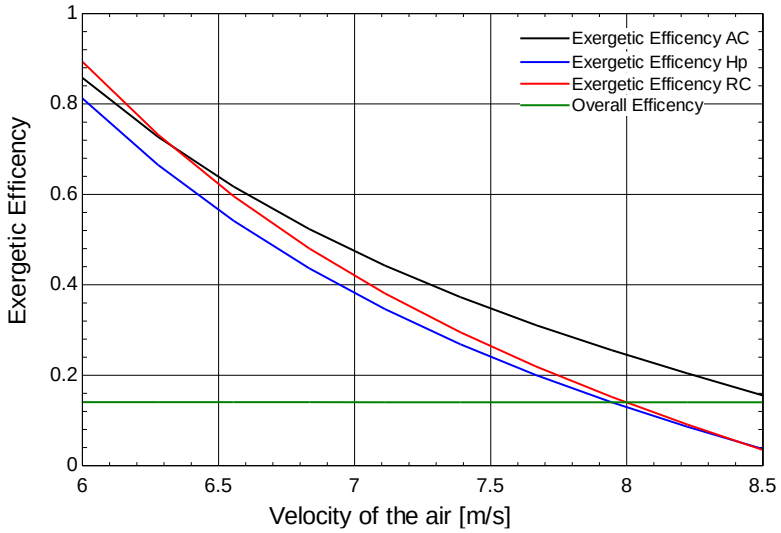

Figure 11. Effect of the velocity of the air on exergetic efficiency of the air-conditioning cycle, heat pump, refrigeration cycle, and overall exergetic efficiency.

Figure 12 shows the relationship between the number of cows on the farm and the exergetic efficiency of the desalination plant, water treatment plant, and overall exergetic efficiency. It can be seen that on increasing the number of cows on the farm from 50 to 120 the overall exergy decreases but later it increases from 120 to 300 and there are two sources which are being powered; one is the desalination plant and the other is the water treatment plant. Overall exergy follows the same trend as for desalination and water treatment. In this case the velocity of the air is kept constant which results in none of the vapor compression cycle varying.

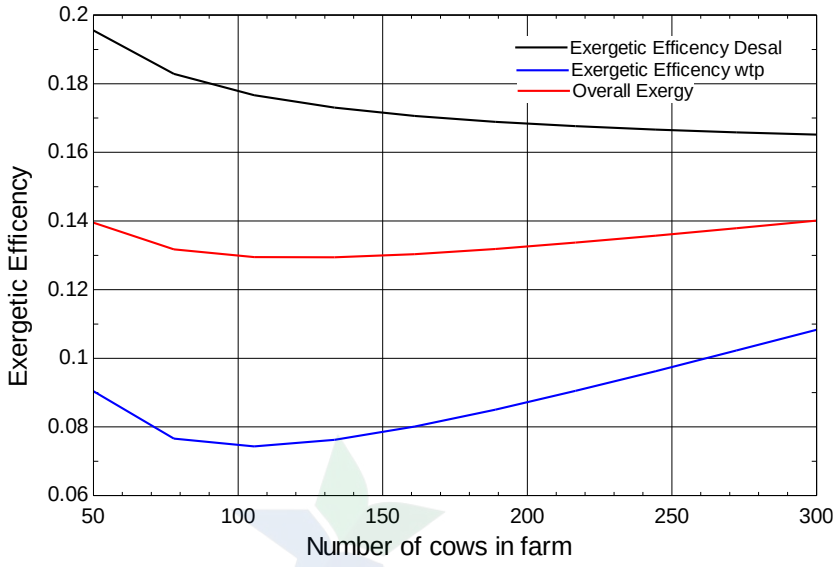

Figure 12. Effect of number of cows on exergetic efficiency of the desalination plant, water-treatment plant, and overall exergetic efficiency.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Figure 13 shows the relationship between the velocity of air and the COP of the air-conditioning cycle, heat pump, and refrigeration cycle. It can be seen that on increasing the velocity of the air the COP of the air-conditioning cycle, heat pump, and refrigeration cycle decreases. For an increase in the velocity of air from 6 m/s to 8 m/s, the COP decreases from 8 to 1.

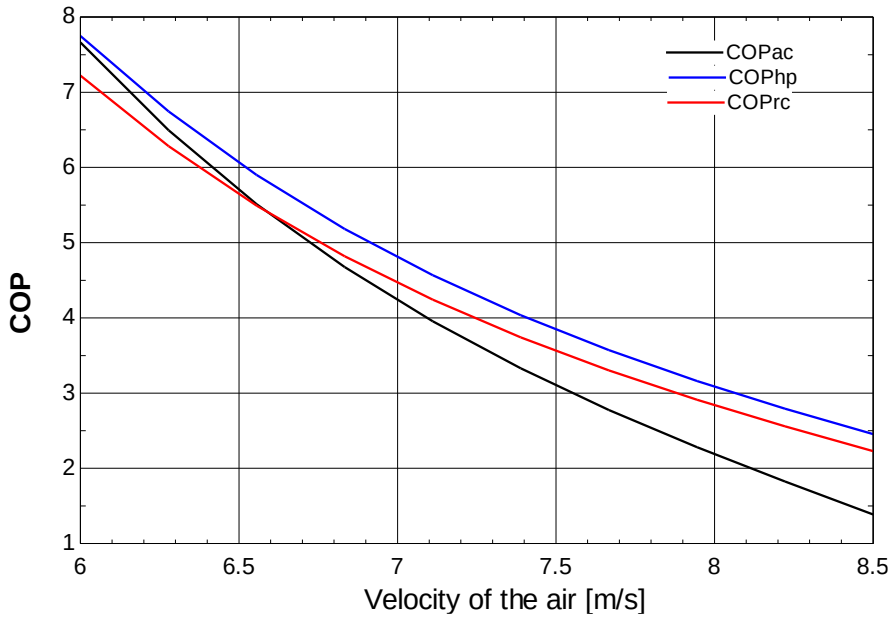

Figure 13. Effect of the velocity of the air on COP of heat pump, refrigeration cycle, and air-conditioning cycle.

Figure 14 shows the relationship between the current and mass flow rate of hydrogen. Most of the power supplied by the wind turbine is consumed for hydrogen production, hence the maximum current is produced; the voltage is kept constant at 2 V for the electrolysis process. It can be observed that with increasing the current the mass flow rate of hydrogen increases. For an increase in current from 0 A to 50 A the mass flow rate of hydrogen increases from 0 to 1.3×10^{-7} kg/s black line. The mass flow rate of oxygen also increases from 0 to 2.5×10^{-8} kg/s green line.

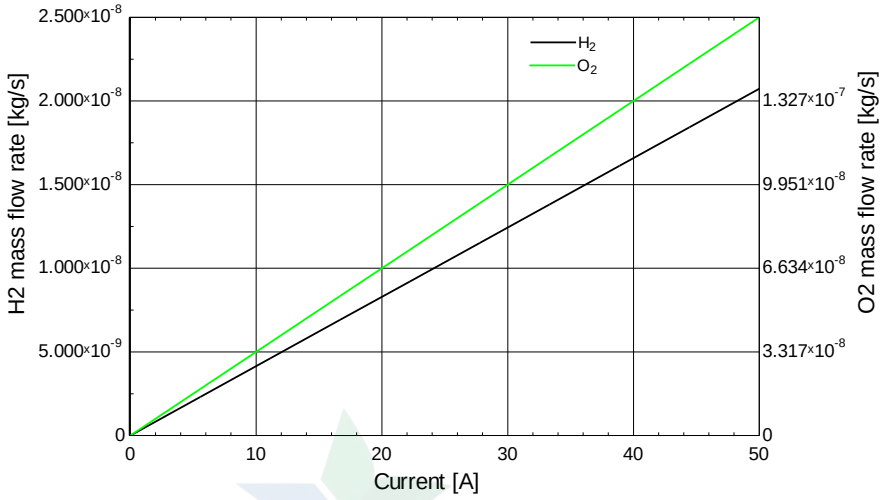

Figure 14. Effect of current on the mass flow rate of hydrogen.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Figure 15 shows the relationship between the number of cows on the farm and the desalinated water flow rate. It can be seen that with increasing the number of cows on the farm the desalinated water flow rate also increases. For an increase in the number of cows on a farm from 50 to 300 the desalinated water flow rate increases from 20 kg/s to 160 kg/s.

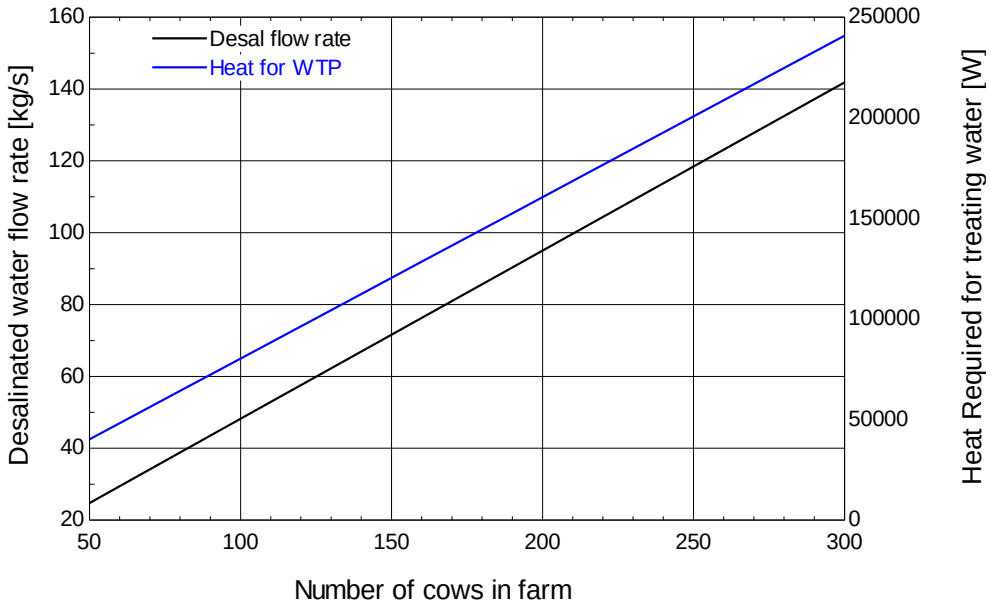

Figure 15. Effect of number of cows on a farm on desalinated water flow rate.

Figure 16 shows the exergy efficiencies of different processes. It can be seen that air-conditioning cycles have the highest exergy efficiency and electrolysis has the lowest exergy efficiency. The exergy efficiencies of air-conditioning, desalination plant, electrolysis process, heat pump, refrigeration cycle, water treatment plant, and overall exergy efficiency are 0.2447, 0.1652, 0.6055, 0.1287, 0.1394, 0.1083, and 0.1401 respectively.

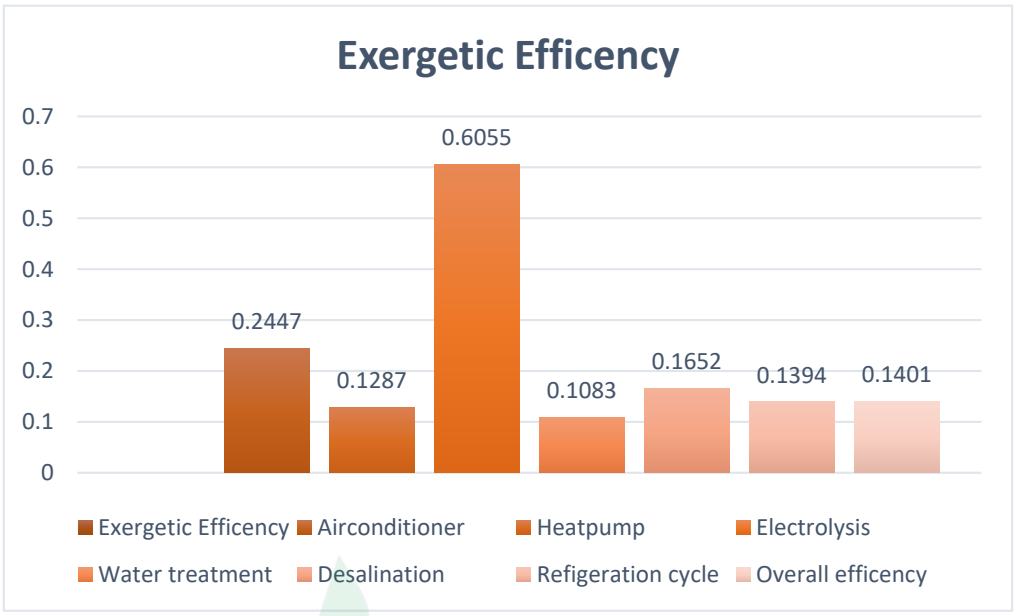

Figure 16. Exergy efficiency of different components.

The root locus method was used to study the stability of the system. If for a bounded input, there is bounded output then the system is said to be stable. If all the poles lie on the

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

right-hand side of the poles zero graphs, then the system is stable. If even a single pole lies on the left-hand side of the graph the system is said to be unstable. Root locus varies the gain of the system and plots the poles zero graphs; it allows the user to analyze and identify the parameters of the control system within which the system should be operated. A transfer function could be either a first-order system, second-order system, or at maximum a third order system for the multigeneration cycle. Hence for heat pumps, air conditioners, refrigeration cycle, and electrolysis, a first-order system is used, while for water treatment, desalination, and for power generation a cycle zero-order system is used.

A PID controller is used to stabilize the system response and make the system respond quickly. The PID autotune function is available in MATLAB which provides the best proportional, integral, derivative, and filter coefficient values for the system. In the case of the air conditioner, these values are P = 1.338, I = 0.08912, D = −1.457, and N = 0.126. Figure 9 shows that earlier the tuned response system was highly unstable and the thermostat was not maintained until 100 s, however, afterwards the tuning system can achieve a steady state in 60 s with negligible oscillations.

In the air-conditioner, refrigeration cycle, and heat pump the first-order system was considered. Figure 17 shows that when the root locus is plotted, it results in a horizontal line on the left side of the zero poles graph. Because all the poles are lying on the right-hand side of the graph then any range of mass flow rates could be applied across these sub-cycles hence the system is stable at any available point. In a study conducted by [28], the response time of the compressor was experimentally and mathematically calculated, and the time constant for the air compressor was observed to be 30 s. Hence 30 s was used as the time constant for the refrigeration cycle transfer function. Figure 18 shows the root locus plot of the vapor compression cycle.

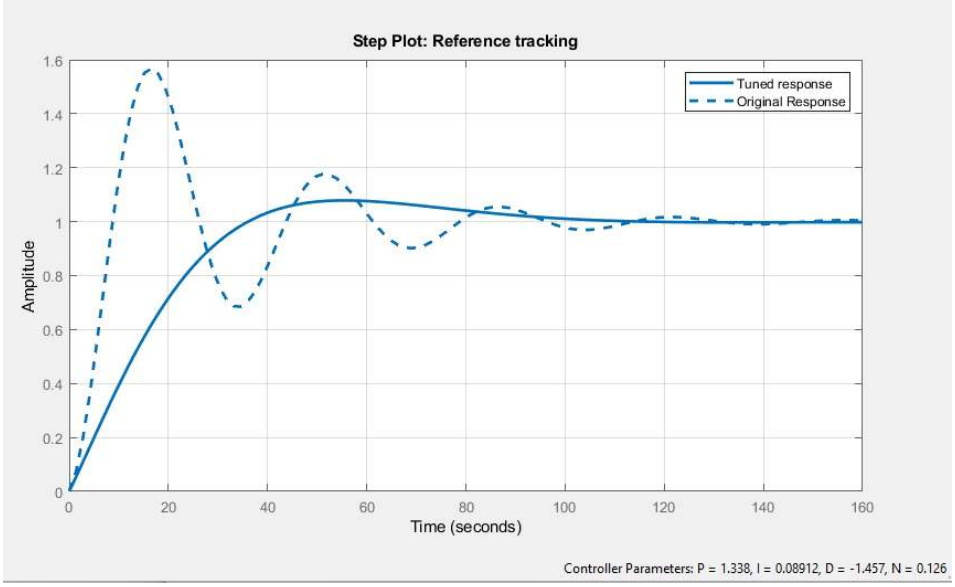

Figure 17. Time response of vapor compression cycle before tuning and after tuning.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

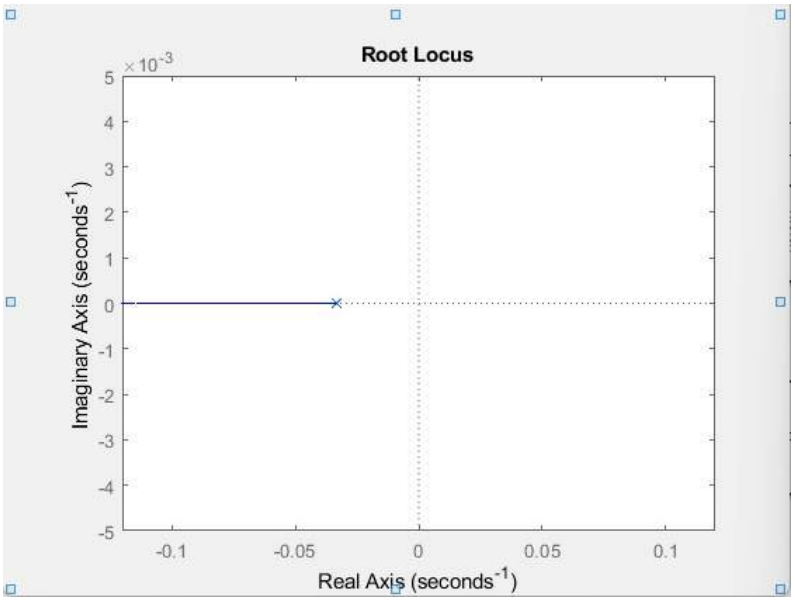

Figure 18. Root locus plot of vapor compression cycle.

For the electrolysis transfer function, the first order system was applied. Electrolysis is performed by supplying DC to a brine solution which results in the production of hydrogen and oxygen gas. The PID was also integrated with electrolysis by Simulink. After tuning, the electrolysis achieved a faster system response and tuned values were obtained as in Figure 19.

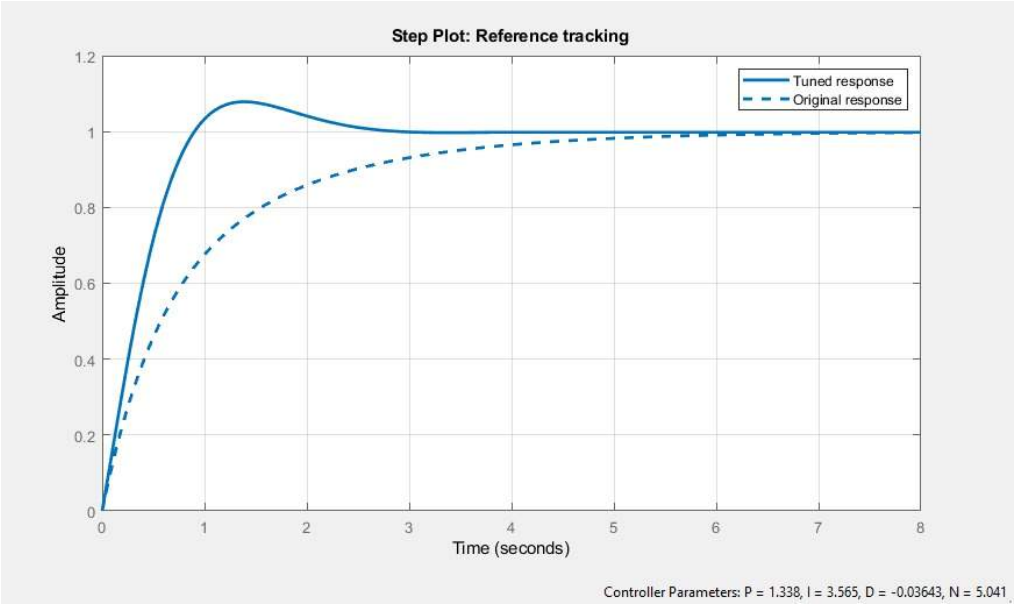

Figure 19. Time response of electrolysis system before tuning and after tuning.

Battery time response has been studied in multiple literature examples. This multi-generation cycle time constant of 0.75 s is in reference to the study by [29] which is used in the Simulink first-order transfer function. Figure 11 shows PID tuned response; obtained values for the tuned response were P = 1.338, I = 3.565, D = −0.03643, and N = 5.041. Before, the tuned response system reaches a steady state at 4 s, afterwards the tuned response system can achieve a steady state at 2 s for the electrolysis system.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Figure 20 shows that when the root locus plot is plotted a horizontal line on the left-hand side of the real axis is generated. Since none of the poles lies on the right side of the pole zero plot, the system is considered stable.

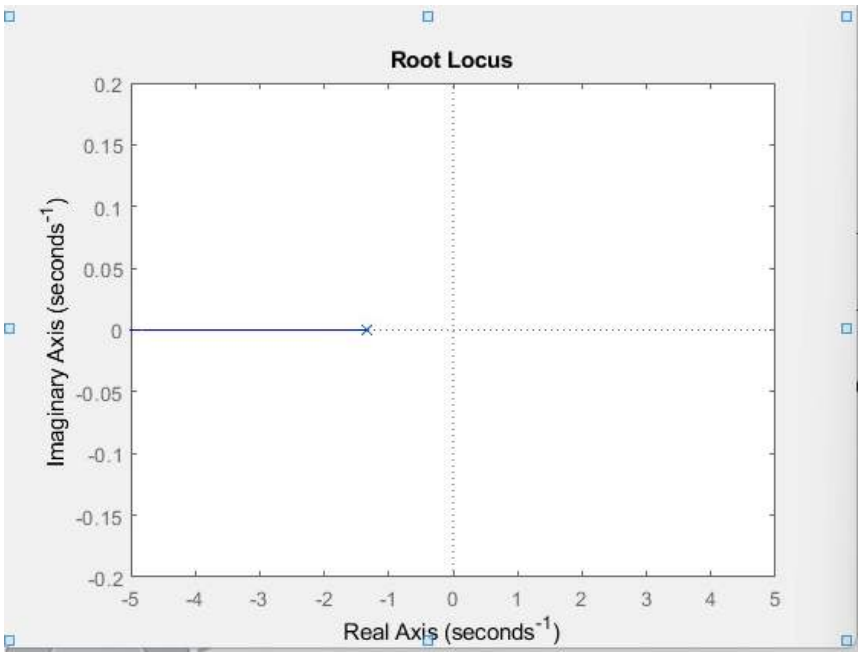

Figure 20. Root locus plot of electrolysis system.

There were several key finding and results obtained from this study. Overall exergetic efficiency for operating this multigeneration cycle was equal to 0.1401. For having wind airspeed of around 7–8 m/s and using biogas produced from the manure of 200–300 cows in a farm, 140 kg/s desalinated water flow rate was obtained, while 5×10^{-7} kg/s of hydrogen gas, and 5×10^{-6} kg/s of oxygen gas were obtained from the electrolysis. The Simulink steady state thermodynamic model was built successfully. In addition, tuned PID parameters were obtained for the individual cycles, and the root locus graph was plotted to determine the stability of the thermodynamic cycles.

4. Discussion

The method used to analyze the multigeneration cycle was performed using the methodology of previous literature. However, the parametric and requirements for this system were different from other studies. To validate the study performed, the system was modeled using the available parameters from the studies. After a comparison of the results, the percentage differences for the gas production, power input, power output, and exergy efficiency from the available literature were obtained. Table 2 shows deviation of the results for the calculations from different sources. Since most of the values are close to each other, the model used tended to generate accurate results like the other similar studies conducted. For the vapor compression cycle, the difference in exergy efficiency is 0.0% from Cengel's [27] vapor compression cycle model. Similarly, for the other cycles like wind power, biogas production, and electrolysis the difference from the literature is negligible. For desalination the thermodynamic model prepared is novel, for this reason energy and exergetic analysis comparison isn't available N/A; this analysis can only be determined by changing the operational standard. A limited library is available for thermodynamic modeling in Simulink. In this study the multigeneration system for sustainable cities was thermodynamically analyzed using both EES and Simulink software. Additionally, the best transfer function obtained for the individual components from the literature was used to obtain steady state response through tuning of the PID controller. Finally, a root locus plot was provided to identify the stability of the processes of the multigeneration system.

Table 2. Validation table for the results obtained.

	Mass H_2/Power Input/Power Output			Exergy Efficiency			Source
	Present	Published	Difference	Present	Published	Difference	
Vapor Compression Cycle	1.81	1.82	0.5%	56%	56%	0.0%	[27]
Wind Power	8100	7792	4.0%	0.8607	0.845	1.8%	[30]
Biogas Production	9430	9391	0.4%	N/A	N/A	N/A	[25]
Electrolysis	0.06561	0.06562	0.015%	0.6054	0.6055	0.017%	[31]
Desalination	N/A	N/A	N/A	N/A	N/A	N/A	[26]

5. Conclusions

For this proposed multigeneration cycle, wind and biogas were used as power generation. For the energetic and exergetic analyses, the cycle was modeled on EES software. The combined exergetic efficiency was equal to 14%; the major contributor to the loss of overall exergy was due to biogas since most of the energy obtained from the biogas is lost. Other results included the COP of the refrigeration cycle and heat pump. The amount of hydrogen and oxygen produced was also calculated for different current cycles. Fresh water was produced using the desalination process and hot water was produced using the heat from the heat exchangers. The cycle was also modeled in Simulink using Python integrated into MATLAB to use the Cool Prop library. After identifying the expected order of the system for each component of the cycle, components were tuned for the PID controller while root locus plots were obtained. Currently, there is a limited library available for thermodynamic modeling in Simulink and for other programming software. The one which is available does not provide accurate readings for some of the refrigerants/working fluids. For future work, the transfer functions could be obtained from the actual compressor, pump, boiler, and heat exchanger to improve accuracy. A better controller could be introduced to improve tuning. In addition, the Simulink model could be improved to model a more complex cycle.

Community-Focused Renewable Energy Transition with Virtual Power Plant in an Australian City—A Case Study

Chengyang Liu, Rebecca Yang *, Kaige Wang and Jiatong Zhang

Solar Energy Application Lab, School of Property, Construction and Project Management, RMIT University, Melbourne, VIC 3000, Australia; chengyang.liu2@rmit.edu.au (C.L.)
* Correspondence: rebecca.yang@rmit.edu.au

Abstract: The global transition to a renewable-powered economy is gaining momentum as renewable energy becomes more cost-effective and energy-efficient. Renewable-energy-integrated Virtual Power Plants (VPPs) are capable of facilitating renewable transition, reducing distributed generator impacts, and creating value for prosumers and communities by producing renewable energy, engaging in the electricity market, and providing electricity network functions. In this paper, we conducted a case study in the City of Greater Bendigo to evaluate the challenges and opportunities of the community-focused renewable energy transition through establishing VPP with community-based renewable generators and storage systems. A reinforcement learning algorithm was formulated to optimise the energy supply, load shifting, and market trading in the VPP system. The proposed VPP system has great potential to improve the economic value and carbon emission reduction performance of local renewable resources: it can reduce 50–70% of the case study city's carbon emissions in 10 years and lower the electricity price from the current range of 0.15 AUD/kWh (off-peak) −0.30 AUD/kWh (peak) as provided by Victorian Essential Services Committee to 0.05 AUD/kWh (off-peak) (peak). Overall, this study proposed a comprehensive framework to investigate community-based VPP in a complex urban environment and validated the capability of the VPP in supporting the renewable transition for Australian communities.

1. Introduction

Cities and their inhabitants consume more than 75% of global energy production and contribute 80% of glasshouse gas emissions [1]. According to the United Nations Department of Economic and Social Affairs (UN DESA), the global population has increased from 751 million in 1950 to 4.2 billion in 2018, with a projected increase to 7 billion by 2050 [2]. With rising population and energy consumption, it is critical to accelerate the energy transition and urban sustainable development.

There are numerous options to improving urban sustainability, including active approaches, such as introducing renewable energy alternatives, and passive approaches, such as demand shift, demand reduction, etc. Among these options, distributed renewable energy (DRE) such as solar photovoltaic (PV) is garnering increasing interest in both research and the market. DRE can (1) reduce carbon emissions, (2) increase energy fairness, supply security, and independence, and (3) minimise dependency on large-scale energy infrastructure investment [3].

However, there are many challenges faced by DRE in urban areas such as limited physical space for installation, compliance with building safety requirements, reduced access to natural resources due to urban density (i.e., reduced solar exposure caused by shading and instable air flow in high-density built areas), the low conversion rate of the DRE system, unstable output of the DRE, impacts to the public electricity grid, etc.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Therefore, a formidable energy management system is essential amid the growth of DRE in the urban environment.

As a novel energy management concept, virtual power plants (VPPs) are gaining increasing research interest. A VPP is a network of distributed generators (DG) and energy storage systems (ESS), in which these integrated elements are able to participate in the energy market as a single entity and own the function similar to a conventional power plant (CPP) by, for example, participating in the electricity wholesale market, providing electricity network services such as ancillary frequency control and load control, or serve as a backup generator in the circumstance of outage.

In contrast to a CPP, a VPP operates differently in several aspects:

(1) A VPP relies heavily on communication and control systems to adjust its dispatch strategies [4,5];
(2) The primary sources of electricity generation in a VPP are distributed energy resources (DERs) located at various locations [6–8];
(3) The participants in a VPP are often referred to as prosumers, as they not only consume electricity but also produce and contribute to the grid [9,10];
(4) VPPs' functionality in the public grid largely relies on energy storage systems which transform the intermittent power flow of the DERs into stabilised and scheduled outputs [11–13].

With the rapid growth of distributed renewable energy systems in the urban environment, it is important to assess the challenges and opportunities of adopting VPPs for effective regulation and management of the DGs. There are several review papers in this field examining the different factors of VPP studies. In 2012, a review paper [14] provided a general overview of VPPs, including their logical framework, control strategies, and optimization. The authors of this paper investigated numerous studies and European VPPs and identified the need for better prediction tools and optimization methods for real-world VPP projects.

A more recent review paper, [15], provided a detailed review of uncertainties involved in the VPP studies. This review identified and discussed three categories of uncertainty: renewable energy generation, market prices, and electricity demand. The authors pointed out that future studies should pay more attention to the structural uncertainties caused by the connection status of DERs. Another review paper [16] summarised the architecture and optimization techniques of VPPs and provided a summary of the best optimization techniques based on operational strategies. Additionally, ref. [17] assessed the risk management strategies adopted in VPP studies and concluded that current VPP studies still have a limited scope regarding risks, which are mostly related to renewable generation and market dynamics.

These review papers highlighted the need for improved prediction tools that are capable of capturing the increasing uncertainties in a broader operating environment of VPPs, optimization methods that are robust under greater complexities of the VPPs' operating strategies, and risk management approaches that provide thorough consideration in a comprehensive spectrum of VPPs' operation goals. Additionally, they suggest the importance of considering uncertainties and the flexibility of VPPs in energy markets. However, most of the previous papers investigated technical benefits and risks from the standpoint of the VPP system itself.

As pointed out in [17], future VPP studies should consider factors beyond technologies or algorithms. VPPs are sophisticated systems that interact with DERs, electricity infrastructure, urban environment, communities, and the end-users. Therefore, the impacts of VPPs require further investigation from the community level with the consideration of the VPPs' costs and benefits, carbon emission reduction capability, and the impacts to the local supply network. VPPs may have the potential to support the constantly growing penetration of DRE systems in cities and reshape the energy landscape of communities by providing cleaner and cheaper energy. However, changes in urban environments can also have significant impacts on VPPs in many ways. Population density, urban planning, and community

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

socioeconomic status play important roles in urban infrastructure [18,19] and may also affect the development and operation of VPPs. Consequently, suitable problem-solving approaches and effective research framework are required to cope with the uncertainties and complexities of deploying VPPs in diverse communities.

Therefore, this study aims to evaluate the challenges and opportunities of community-focused renewable energy transition through the establishment of VPPs with community-based renewable generators and storage systems. A case study was performed for community-based VPPs with a sample size of 235 communities. A detailed modelling and information capturing was carried out using geospatial analyses and K-Means Clustering, to capture and describe the renewable energy resources and supply and demand profiles. Reinforcement learning was selected as the optimisation and control solution to tackle the uncertainties and complexities of the case study communities' diverse demand and supply conditions. This paper is structured as follows: The rest of Section 1 presents a literature review on the present studies of VPPs in terms of VPP operation strategies, modelling, and problem-solving techniques. Section 2 covers the research design and the process of implementing the VPP framework in the case study. The detailed research methods and processes are presented in Section 3, followed by the findings and discussion in Section 4. Finally, Section 5 discusses the conclusion of this study along with research limitations and recommendations for future work.

1.1. Literature Review

1.1.1. VPPs' Risks and Benefits for Prosumers and Communities

VPP development and operation is a multi-party process involving service providers, consumers, prosumers, legislators, and local communities. However, the majority of the previously stated profit-enhancing or risk-reduction measures are primarily applicable to VPP systems or VPP operators [20]. Although it is critical to ensure that VPPs perform optimally when participating in the electricity market, the success of VPPs is largely dependent on the participation and interaction of all stakeholders, as an electricity supply system that may involve substantial investment and significant impacts on urban development [21].

The previous studies in this domain mostly focus on investigating the economic potential of VPPs by optimising their operation strategies in the energy market. For example, [22,23] provided the optimisation of a VPP's profitability of participating in the energy market through frequency control ancillary services and energy trading. The authors of [24–26] investigated the optimisation of the VPP system's operation cost and penalty due to system instability, while [27,28] evaluated the VPP's cost and benefits through reducing greenhouse gas emission.

Although the previous research has developed a comprehensive understanding of the benefits of VPPs as an entity, there is a lack of consideration for the benefits and risks for end-users and communities where the VPPs are based. The participation of prosumers and the communities is one of the essential criteria in the implementation of VPPs [29], for its reliance on the cooperation and aggregation of distributed prosumers. However, in most previous research, the end-users in the VPP framework are considered as flexible loads [13,30] or simply as the source of revenue for the VPP entities.

Distributed renewable energy systems face challenges in achieving commercial viability due to their low capacity and unstable output, as summarised in [31]. Without a well-performing control and optimisation strategy, these distributed resources can also have negative impacts on the public grid, which may require extra costs for balancing supply and demand [32–34]. Furthermore, DRE systems heavily rely on energy storage systems [3], which can significantly increase costs [32]. These economic uncertainties can pose potential economic risks to the communities and end-users greatly, and hinder the renewable transition.

VPPs can play a crucial role in reducing the economic risks of renewable energy through effective management of DRE systems [17]. By integrating DRE systems into the public grid, VPPs can also contribute to reducing overall electricity prices in the market,

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

making renewable energy more affordable for all. In particular, communities with limited purchasing power may benefit from access to cheaper and cleaner energy by participating in VPP networks. Hence, it is essential to gain a deeper understanding of the potential role that VPPs can play in powering communities with distributed renewable resources.

1.1.2. Modelling and Problem-Solving Techniques in VPP Studies

As an energy system interacting with various demand patterns, generation patterns and energy market conditions, the modelling of VPP involves numerous uncertainties such as weather forecasting, demand forecasting, market price forecasting, etc. [15]. The two commonly adopted modelling methods are deterministic modelling, which create sophisticated calculation models for renewable energy systems, the VPP control system, user demand, and energy market [24,35], and stochastic modelling, which represents the VPP components with probability models [22,36,37]. In addition, some studies also use actual data records of generators' output or user demand instead of modelling them [30].

In terms of problem-solving methods such as optimisation and control strategies, the commonly used approaches can be categorised as heuristic approaches and mathematical approaches. Mathematical approaches, such as linear or nonlinear programming, usually adopt regression methods to seek the global or local optimality within the VPP's operation constraints [38,39]. Although these mathematical optimisation approaches are well-developed methodologies, their application to VPP is under critique due to their vulnerability when dealing with uncertainties and their insensitivity to the global optimality [13,15].

Heuristic approaches, such as particle swam optimization, agent-based optimisation, machine-learning-based heuristic control, and optimisation, have more flexibility when dealing with uncertainties and can identify the global optimal more easily [40]. However, as pointed out in [13], these methods may be ineffective for achieving local optimal. This is due to the fact that, given a small population size, the optimisation algorithm typically treats significant contingency events, such as demand spikes and market price spikes, as outliers, despite the fact that these contingencies may be essential for enhancing the energy conservation and economic performance of the VPP.

In addition, with increasing renewable energy options, technique innovation, and a complex operation environment, it was found in [13] that the modelling process for the VPP system is increasing in complexity. Hence, a more robust and effective problem-solving and modelling approach should be introduced to provide optimised decision-making for VPP implementation. As a branch of machine learning, reinforcement learning (RL) is a potent tool for assisting decision making in dynamic situations. RL approaches can provide robust optimisation for different scenarios [41,42] in the application of energy network control and optimisation.

1.1.3. Summary of Literature Review

To sum up the findings of the literature review, it is found that although previous studies in the domain of VPP made significant contributions in investigating the optimisation of VPP operations with various mathematical or heuristic approaches, most of these studies have a limited focus on the VPP's benefits and profitability for the VPP system itself or the operator of the VPP. The risks and benefits for end-users and local communities are rarely discussed. Additionally, current problem-solving techniques for VPP research have met their limitations in dealing with the growing uncertainties and complexities of implementing VPP in urban environments. To address these research gaps and limitations through this research, we conducted a case study in an Australian city with a novel RL-based VPP framework. The case study evaluated VPP's performance in carbon emission reduction, profitability, and benefits for end-users.

1.2. Research Contributions

VPPs operate in complex and uncertain environments, where temporal and spatial dynamics such as supply/demand conditions, demographic profiles, renewable energy resources, urban growth, population growth, and corresponding demand growth can significantly impact their performance. The implementation of VPPs also faces broader challenges and uncertainties, such as long-term economic viability and socioeconomic values, which require in-depth analyses of VPP operations in urban environments. Therefore, a comprehensive understanding of the operational complexities and potential impacts of VPPs is crucial to ensure their effectiveness and sustainability in the long run. Hence, this study aims to further explore the challenges and opportunities of using VPPs in an Australian city's context. The main research objectives of this study are:

(1) To implement a conceptual VPP framework in an Australian city;
(2) To model the VPP's performance for urban communities across an Australian city;
(3) To optimise VPP performance for urban communities across an Australian city;
(4) To evaluate the technoeconomic impacts of VPP and provide discussion and suggestions for future development and policy making

The significance of this study can be summarised into the following two aspects: (1) This study focuses on the research gaps on community-oriented VPP operation and addresses technoeconomic opportunities and challenges for communities and end-users. (2) This study proposes a research framework in the context of community environment and utilises a multi-disciplinary approach to address the uncertainties and complexities.

2. Case Study of Community-Based VPPs

2.1. VPP Implementation Case Study in an Australian City

To investigate the VPP's efficacy in supporting the community-based renewable energy transition, we conducted a case study in the urban area of the City of Greater Bendigo. The City of Greater Bendigo is located near the geographical centre of Victoria, Australia [43], and is the third largest city in Victoria. The urban and rural areas of Bendigo cover nearly 3000 km^2 [44] and are home to 111 thousand people [45]. The City of Greater Bendigo has a strong commitment towards sustainable urban environment. According to an environment strategy report by the City Council of Bendigo, the city encourages the transition to sustainable urban development and has a target to achieve 100% renewable energy in 20 years. However, it is unclear how the renewable systems can deliver the expected effects in carbon reduction and economic viability. In addition, most of the distributed PV and home battery systems have low visibility to the grid operator, which poses a challenge to the grid's stability and brings more uncertainties for future planning on the electricity supply infrastructure.

In this research, we adopt statistical area level 1 (SA1) as the community unit for modelling and data analysis. The statistical area hierarchy is introduced in Australian Statistical Geography Standard (ASGS) [46] to reflect the social geographic location of people and communities. Among the statistical area hierarchy, SA1 is designed to maximise the geographic detail available for Census of Population and Housing data while maintaining confidentiality. This study covers an area of 235 SA1s in the City of Greater Bendigo (Figure 1). The study area is limited by the light detection and ranging data (LiDAR) coverage area in the City of Greater Bendigo. The LiDAR data collected on March 2020 by the Department of Environment, Land, Water and Planning (DELWP) covers in total 235 SA1s of the City of Greater Bendigo. The LiDAR data were used to identify and measure the rooftop PV coverage, urban solar potential, building parameters, and shading impacts.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

2.2. Implementing a VPP Research Framework in Community Context

To conduct the case study, a research framework was designed to implement the VPP network in the City of Greater Bendigo (Figure 2). To provide comprehensive analyses of the VPP implementation with the local communities' urban environment conditions, supply–demand conditions, and socioeconomic and demographic profiles, this research employed multiple methods including geospatial information system (GIS) processing and analysis, system modelling, demand data mining, and reinforcement learning.

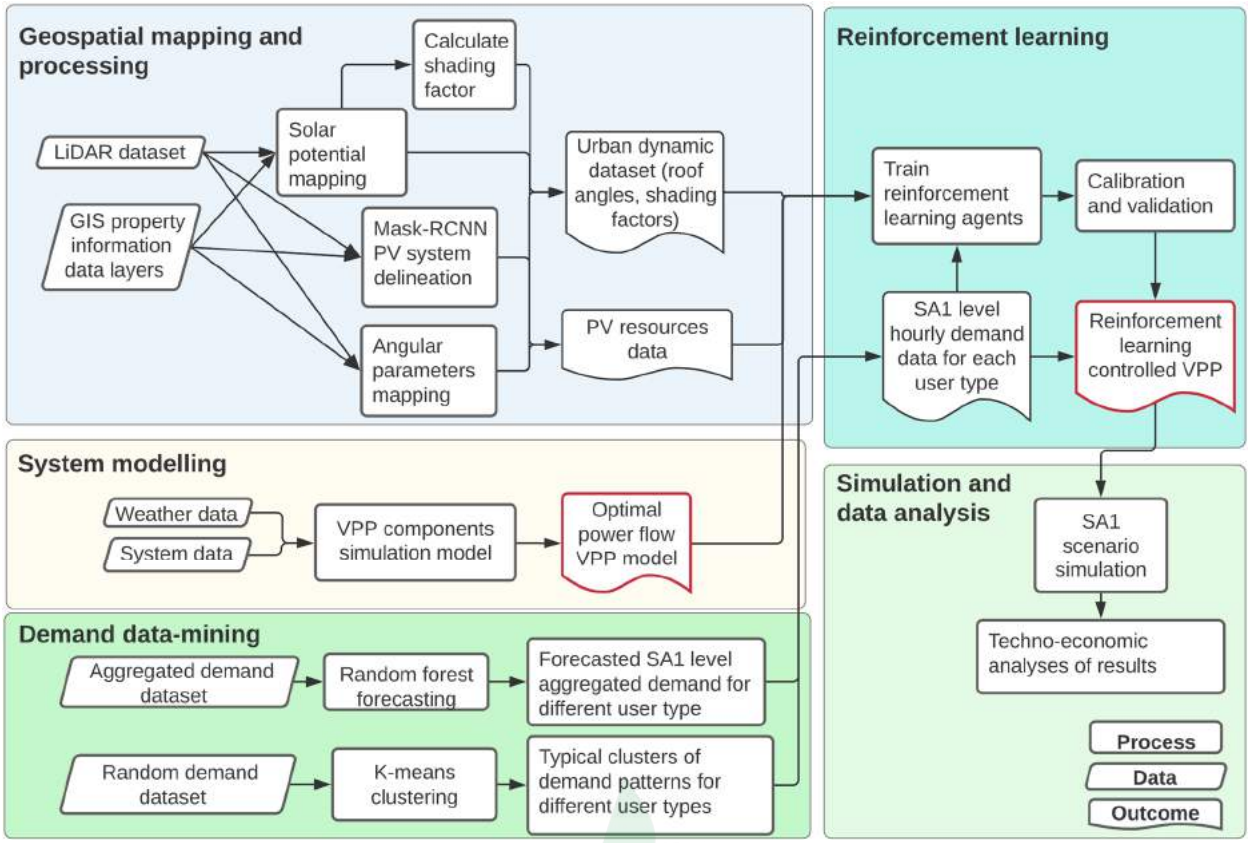

Figure 2. Summary of the research process.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

The research process involved four main steps. Firstly, VPP components were modelled and the supply and demand conditions of multiple communities were characterised using geospatial mapping, demand data mining, and system modelling. Secondly, a reinforcement learning control system was established and trained using random populated sample supply/demand, PV output, and market data to adopt the optimal distributed resources management policy. Thirdly, the trained RL models were deployed to the communities. The VPP simulations were carried out within each of the 235 communities under multiple scenarios of renewable resources and battery capacity. The VPP operation considered the interaction of communities' load, storage capacity, PV generation, and electricity market at an hourly interval. Finally, technoeconomic analyses were conducted to evaluate the VPP's performance in terms of carbon emissions, economic impact, and grid impacts. The detailed process of steps 1–3 is covered in Section 3 and the data analyses results and discussion are presented in Section 4.

3. Data Processing, Modelling, Optimisation, and Simulation for Community-Based VPPs

3.1. Geospatial Mapping and Processing

GIS is a powerful tool which facilitates a better understanding of urban environment dynamics and local resource distribution. In this part of the study, GIS data on the City of Greater Bendigo were collected, and GIS platforms (QGIS and ArcGIS) and processing tools were adopted to analyse the geographic data and map the urban environment and PV resources. In this study, the GIS data were collected from the Department of Environment, Land, Water and Planning (DELWP) of the Victoria State Government. The dataset includes the LiDAR data of digital surface model (DSM), high resolution aerial image, building height model (BHM), and property footprint. The DSM data were used to create the case study city's roof angular profile including azimuth (Figure 3) and tilt angle (Figure 4).

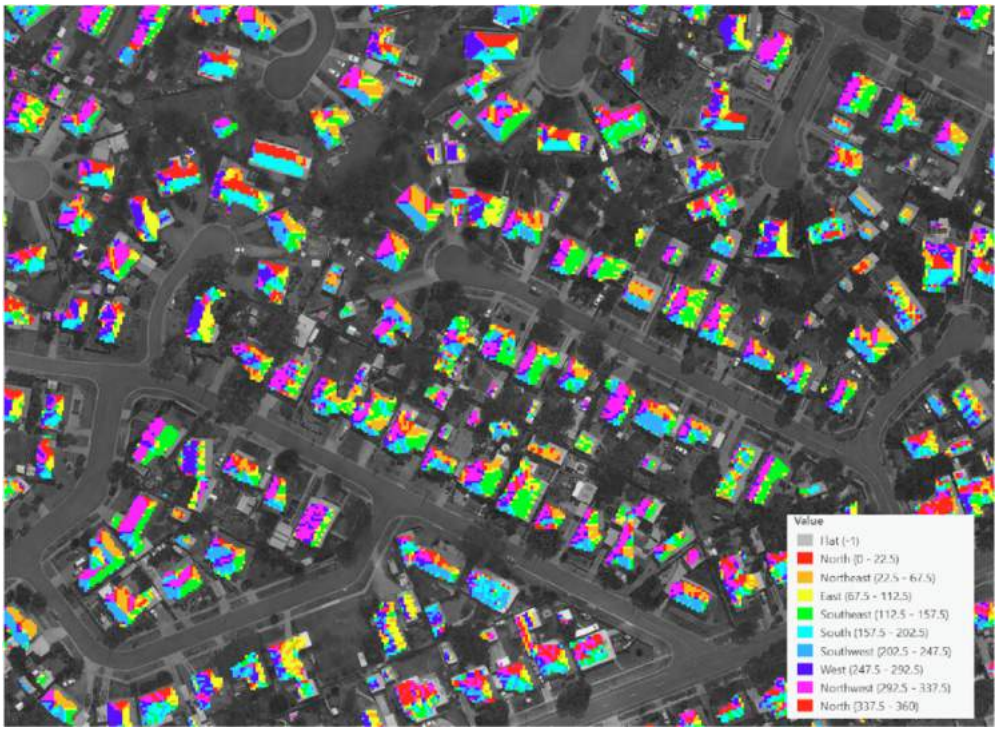

Figure 3. Roof azimuth angle raster layer calculated using BHM and QGIS Aspect function.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

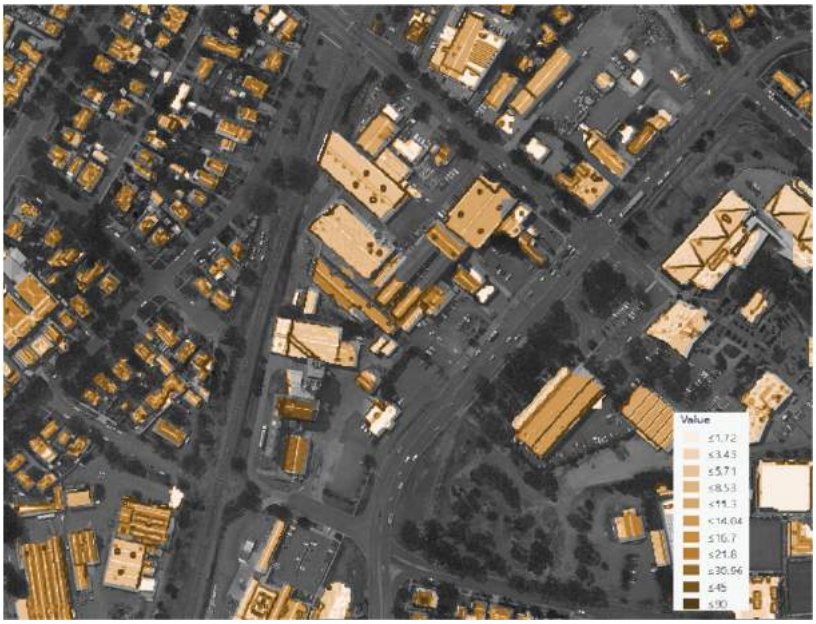

Figure 4. Roof tilt angle raster layer calculated using BHM and QGIS Slope function.

BHM was used as an input raster to determine the azimuth angles of building rooftops. The aspect function in the QGIS toolkit was used to generate the azimuth angle raster layers. A rooftop's azimuth angle (aspect) is its angle of departure from north (0°). It has a range of 0 to 360 degrees, with 0 representing north and 180 degrees indicating south. The aspect function in QGIS returns the azimuth distribution of the input BHM (Figure 3). The azimuth raster was coloured to illustrate different angular values. Each rooftop's azimuth angle was then exported as an attribute table, which was subsequently utilised to simulate rooftop PV.

The tilt angle, like the azimuth angle, is an important angular parameter for simulating PV output. The Slope function in QGIS takes the BHM as input and generates the rooftop tilt angle layer. The tilt angle layer, like the azimuth angle layer, was coloured to show the angle values (Figure 4).

Furthermore, GIS-based approaches were used to identify both existing and potential solar PV resources in the case study city. With the high-resolution aerial image data and the Mask R-CNN [47] image recognition algorithm, the existing PV systems installed on Bendigo rooftops were delineated. Based on the angular parameter and shading impact factor, the solar PV potential mapping of the rooftop PV in the case study area was created (Figure 5). The GIS processing outcome of PV delineation, azimuth angle, tilt angle, and potential mapping was used in the following sections for PV modelling and simulation.

Figure 5. Rooftop solar irradiation potential raster.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

3.2. System Modelling

The system modelling in this study comprises the modelling of the PV system, battery energy storage system (BESS), the control mechanism of the VPP, and the energy market. The modelling was carried out using MATLAB and Simulink. To simulate the operation of the PV system, the following factors were taken into consideration: (1) Plane of array (POA) irradiance; (2) Solar position; (3) Losses caused by heat transfer; (4) Losses caused by the inverter, mismatch, wiring, shading, dust, etc. On the one hand, POA irradiance, solar position, and heat loss are closely related to the GIS-defined urban environment profile, which was sophisticatedly modelled to enable the analysis of different input scenarios. The model adopted the PVlib toolbox developed by Sandia National Lab [48]. The modelling of a storage system mainly requires inputs of system specifications such as charge/discharge rate, maximum capacity, and efficiency. The reference value for BESS is based on the specifications of the TESLA Powerwall [49].

3.3. Demand Data Mining

Energy consumption data were provided by the case study city's local distribution network service provider: PowerCor. The dataset included an aggregated customer-type-based dataset for postal areas and 3000 de-identified samples with categories of different property purposes: residential, commercial, industrial, agricultural (coded as R, C, I, and A, respectively). A data-mining approach integrating Random Forest (RF) and *K*-means Clustering was used to extract the features of the sample demand data and reconstruct the demand dataset for the four user types in each SA1 cluster.

The data mining process comprised the following steps: (1) Train the RF model with sample postal-area-level input features and validate the results at the postal area level, (2) Establish the RF forecasting model on expanded postal-area-level input features and validate the results at the postal area level, (3) Train the RF model on postal-area-level input features to forecast the SA1-level consumption profile, (4) *K*-means clustering of the de-identified sample to extract the consumption profile for each type of user, and (5) Reconstruct SA1-level demand patterns based on clustered profiles and the forecasted SA1-level consumption profile.

Additional input variables of the user type composition, population density, and dwelling density for each SA1 and postal area were acquired from ABS to create a prediction model with RF that could estimate a SA1-level aggregated consumption profile from postal area demand data. The following input features were labelled on the aggregated postal area demand data: (1) Season, (2) User type, (3) User type count, and (4) User type ratio.

The *K*-means approach was adopted for the clustering of the random sample data to identify the typical demand patterns among different user types in the City of Greater Bendigo. *K*-means is one of the most fundamental but efficient unsupervised learning algorithms for data mining [50]. The goal of *K*-means clustering is to seek the optimal clustering policy that has the minimal total squared errors across all defined clusters, which can be described using the following equations:

$$E_K(a, b) = \sqrt{\sum_{i=1}^{n} (a - b_i)^2} \quad (1)$$

where, E_K is the Euclidean distance of each cluster, a is the cluster mean, and b_i are the members of the defined cluster. The objective of the *K*-means approach is to minimise the aggregated E across all K clusters:

$$\min(E_K) = \sum_{j=1}^{K} E_K(a, b) \quad (2)$$

The process of using *K*-means clustering to establish typical demand patterns is shown in Figure 6. The dataset was divided into four sections by user type during the pre-processing stage. Following that, each sub-dataset was divided into four seasons, which generated sixteen independent datasets. The K parameter should be established

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

after the sixteen independent datasets are ready for clustering. Because the goal of *K*-means clustering is to minimise total squared errors across all clusters, inertia analysis was performed to calculate the within-cluster sum of squared errors (WCSS). In the inertia analysis, the WCSSs in each *K* were displayed in a line chart to show the reduction in inertia. A suitable *K* divides the dataset into *K* clusters, resulting in a considerable reduction in inertia when compared to the inertia in *K* 1 clusters. Following the selection of *K*, each independent dataset was grouped into *K* clusters using the *K*-means algorithm. Each cluster indicates a group of people who have the same customer type and use similar amounts of electricity during a given season.

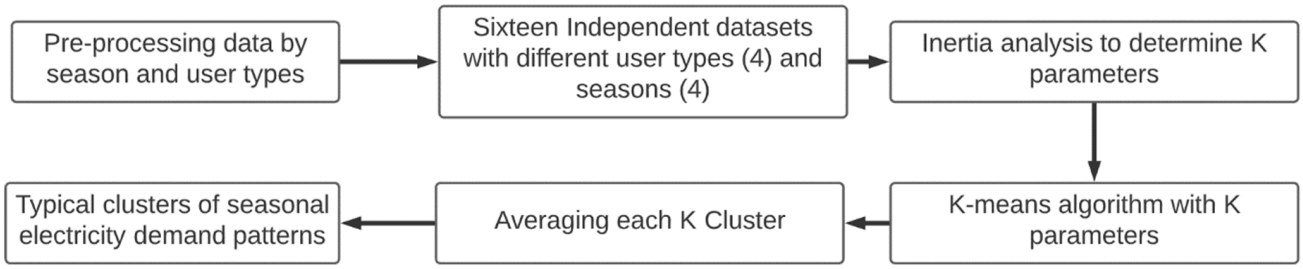

Figure 6. Establishing typical seasonal SA1 demand profiles with *K*-means.

Shown in Figure 7 is a sample of the reconstructed demand pattern. Each row of Figure 7 shows one month's electricity demand profile (kWh) for all residential users in one sample SA1. The outcome is the hourly interval demand data for each type of user in each SA1 of the City of Greater Bendigo. The reconstructed hourly demand pattern was then amplified to fit the aggregated SA1 electricity consumption in each SA1 for each user type. The models used in the demand data mining process were cross-validated multiple times at the postal area level to ensure its efficacy as far as possible. However, it remains a limitation that the true fidelity of this approach cannot be verified on a more detailed level (i.e., SA1 level), due to the lack of ground truth data at the SA1 level and the de-identification of the sample user data.

3.4. Reinforcement Learning VPP Operation Model

To operate the VPP under uncertainties and complexities in the urban environment and provide optimised control decisions, this study applied an RL-based approach to model the VPP control system. The concept of RL is very similar to human behaviour patterns when we observe and learn about the world. We learn something by obtaining sufficient positive feedback and learn that something is incorrect or dangerous by receiving negative feedback. Similar to human learning, the foundation of RL is the Markov Decision Process (MDP), which defines the procedure by which RL agents interact with the environment. MDP provides a control model for decision making in a discrete and stochastic process. The MDP creates an environment for the decision maker, in our case, an artificial intelligent entity (agent). In the MDP environment, the agent generates actions to change the states of the environment randomly. The changes result in the reward the agent can obtain and the probabilities of future state transitions. The agent's objective is to select actions to maximise the long-term measure of total reward.

In this study, the RL-controlled VPP system is capable of adjusting electricity trading and scheduling strategies based on the observation and forecast of the users' demand, the national energy market (NEM) electricity price for wholesale and ancillary services, and the renewable energy systems' output. In total, four RL agents were trained under the four demand patterns, namely A, C, I, and R. The RL agent applies the deep deterministic policy gradient (DDPG) algorithm to construct its deep neural network through training iterations. The VPP system structure was modelled in Simulink with a MDP environment embedded. The RL system's objective function is to maximise the economic benefits and minimise the

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

losses in the operation of a VPP by providing demand shifting and participating in the electricity market. The objective function can be formulated as the following equation:

$$max\ CF = \sum_{t=1}^{T} p_{vpp}(t) \times k_{market}(t) + abs(p_{ancillery}\ (t)) \times k_{ancillery}\ (t) \quad (3)$$

where CF is the total cashflow of all timesteps, $k_{market}(t)$ is the AEMO-recommended retail price used to estimate the cash flow for trading with the public grid, and $k_{ancillery}\ (t)$ is the AEMO ancillary services market price used for estimating ancillary services incomes.

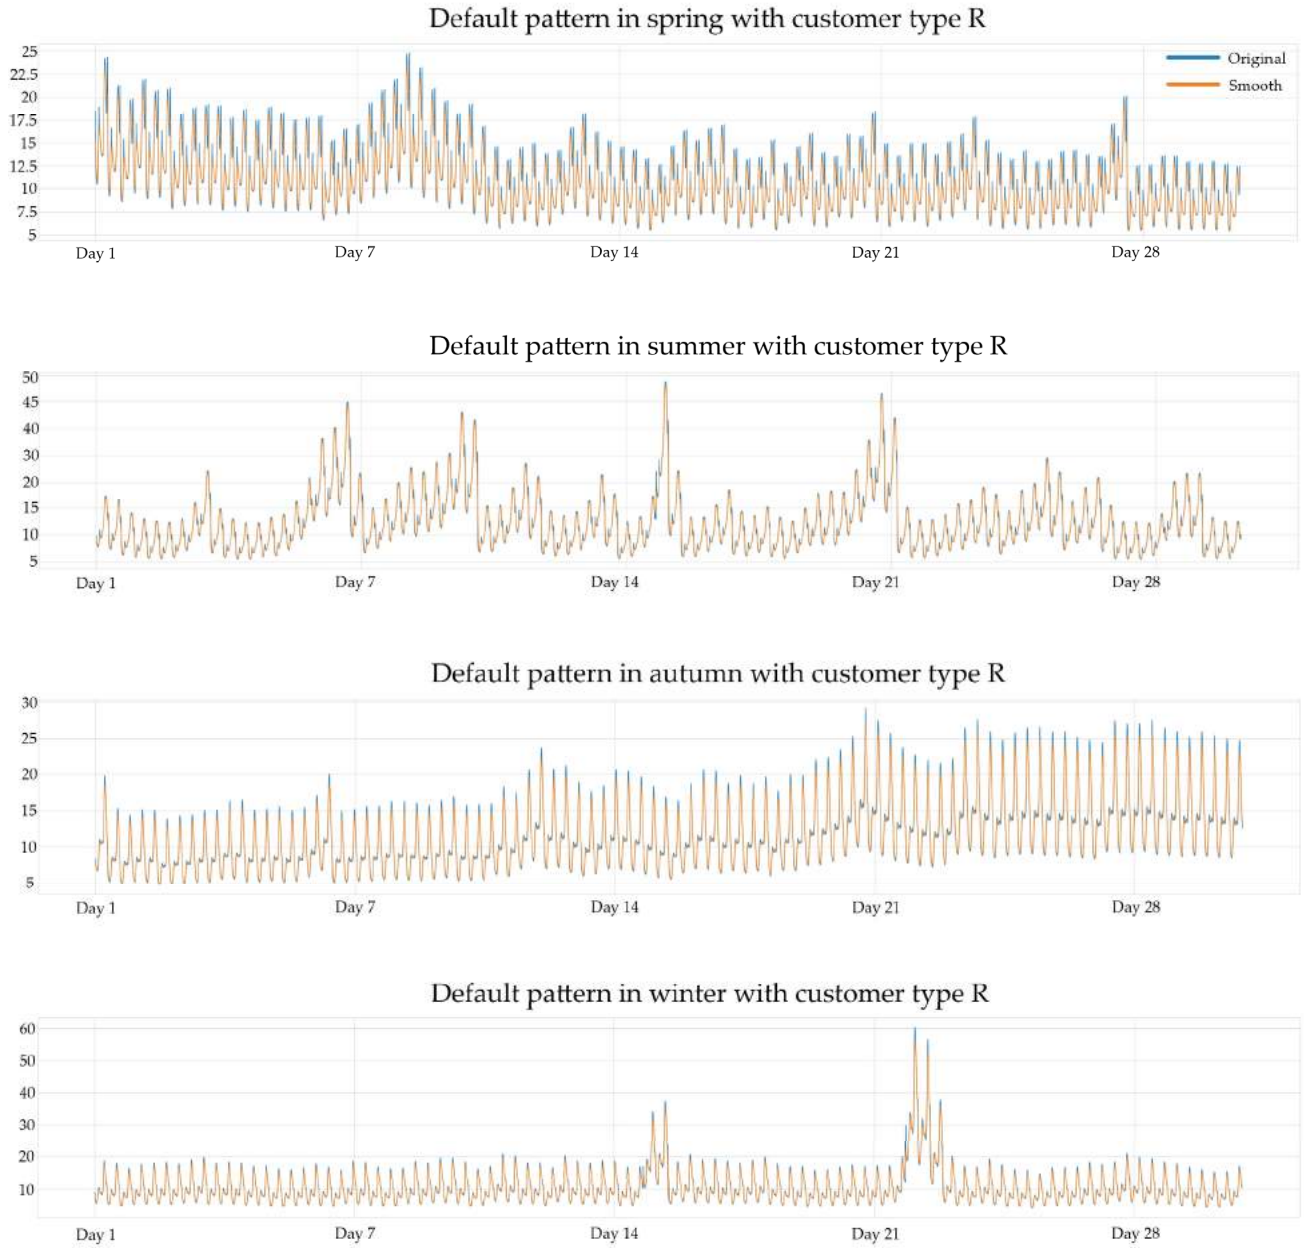

Figure 7. Sample reconstructed SA1 level demand pattern for residential users in four seasons (kWh).

With the objective function defined, the reward function for the RL system can then be formulated with the following three components: (1) the objective reward (R_{obj}), (2) the step reward (R_{move}), and (3) the finishing reward (R_{madeit}). The reward function for the RL system can be described as:

$$max\ R = \sum_{t=1}^{T} [R_{obj}(t) + R_{move}(\mathrm{t})] + R_{madeit} \quad (4)$$

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

R_{obj} is modified from the objective function (Equation (4)) to represent the actual cash flow of the VPP system.

3.5. Multi-Scenario Simulation and Analysis

The multiple scenario analysis of this study simulated and investigated the impacts of different VPP operation strategies under the different scenario cases. When generating scenario cases, this research considered the spatial and temporal dynamics of the urban environment in terms of the demand/supply changes, market changes, etc. The following aspects were considered in the scenario settings:

Scenario group A: Scenarios of potential PV coverage

Based on the PV system delineation results, the PV coverage scenario was established, considering solar potential, rooftop orientation, the slope of the roof, and the rooftops' financial viability for deploying PV systems. The scenarios were as follows: (1) Base case with currently detected solar panels, (2) Medium coverage ratio scenario (25% of total available rooftop), (3) High coverage ratio scenario (50% of total available rooftop).

Scenario group B: Scenarios of electricity storage facilities

The PV/battery ratio is an essential factor to be considered when designing a distributed PV system. Many studies have investigated the coverage ratio impact of PV systems and battery systems on self-sufficiency capability and economic performance [51–54]. However, most of these studies applied scenario analyses that investigate different ratios' performance. The recommended ratio ranges from 50% to 200%, as can be found in these studies. Based on a recommended system ratio from an Australian State Government document, the baseline ratio in this research was set for 70% of the PV system capacity [55]. For scenario group B, three cases were introduced: (1) base case scenario without battery capacity, which affects the base case VPP operation scenario only, (2) battery capacity of 70% PV capacity, (3) battery capacity of 140% PV capacity, and (4) battery capacity with 210% PV capacity.

Scenario group C: Scenarios for electricity demand growth

This study considered a demand growth of 5 years to reflect the future demand conditions. The current demand is based on the demand data as introduced in Section 3.3. The 5 years' demand growth is forecasted using the estimated demand growth rate recommended by Australian Department of Industry, Science, Energy and Resources (DISER) [56]. In the DISER's 2020 report, the recent growth rate for 2019–2020 is used to estimate the five years' growth in the near future.

4. Findings and Discussions

This section discusses the feasibility of a distributed renewable energy management system—VPP from the following aspects: (1) Carbon emission reduction, (2) Project economic performance, (3) User electricity price reduction and (4) Consumption efficiency measured by load factor.

4.1. Carbon Emission Reduction Performance of VPPs

Figure 8 presents the histogram of the simulation results of carbon emission reduction ($CO_{2\text{-e}}$) with VPP implemented in each SA1. The emission reduction was calculated using Equation (5), where C_{e-VPP} is the emission of CO_2 with VPP implemented, $C_{e-Total}$ is the total CO_2 emission, and C_{e-R} is the emission reduction rate:

$$C_{e-R} = \left(1 - \frac{C_{e-VPP}}{C_{e-Total}}\right) \times 100\% \quad (5)$$

The carbon emission reduction factor was calculated based on the carbon dioxide (CO_2) emission factor provided in [57] for electricity purchased from the grid. According to the report, in Victoria, Australia, the emission factor for CO_2 is 0.98 kg/kWh. As can be seen in Figure 8, with low PV coverage levels, the vast majority of SA1s have carbon emission reduction rates lower than 10%, and the frequency of the 0–10% group increases while

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

the demand growth scenario changes from current to future years. Increased PV coverage scenarios have a significant effect in increasing the rate of reduction of CO_2 emissions. It can also be noticed that within the same PV coverage scenario, increasing BESS capacity enlarges the group size of SA1s with higher carbon emission reduction rates.

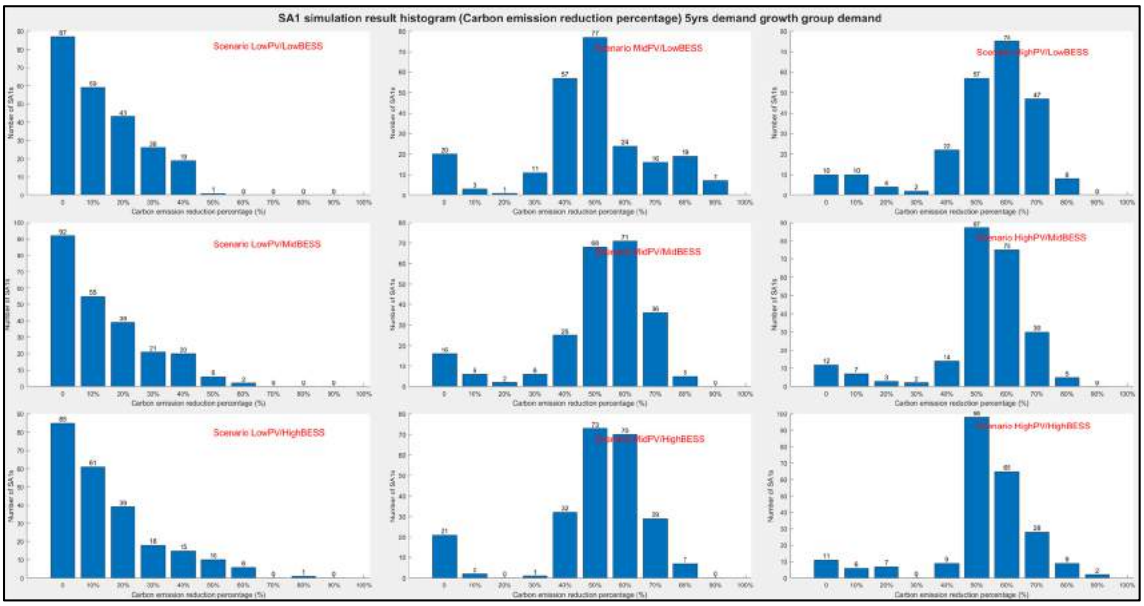

Figure 8. Histogram plots of SA1 simulation results for carbon emission reduction rate.

Figure 8 presents the histogram plots of SA1 communities' carbon emission reduction rate under different VPP operation scenarios. The X-axis represents the 10% interval of carbon emission reduction rates being measured. The Y-axis represents the count of observations that fall within each interval.

Based on Figure 8, VPPs have the potential to reduce communities' reliance on fossil fuel-based electricity. However, this capability depends on the capacity of available PV and BESS in the VPP systems. Furthermore, the figure shows that even with medium or high levels of PV coverage, around 20–30 communities in the second and third columns have low carbon emission reduction rates of less than 20%. This is likely due to extreme consumption levels in some industry or agriculture-focused communities that cannot be effectively offset by renewable generation. Therefore, while VPPs perform well in most communities with higher renewable energy and storage penetration, they may not be a one-size-fits-all solution for all communities with various demand patterns. Future investments and policy making should consider each community's suitability when evaluating VPP as a carbon emission reduction approach.

4.2. Economic Performance of VPPs Measured by 25 Years Net Present Value (NPV)

As presented in Section 4.1, the VPPs tend to have a better performance among the communities when exposed to more renewable resources and BESS capacity. Nevertheless, the increasing size of distributed PV and BESS will involve a greater amount of capital investment. Hence, it is essential to examine VPPs' costs and benefits among the multiple scenarios.

To measure the financial viability of investing in VPPs, this study calculated the VPP project's life cycle net present value (NPV) for each SA1. The NPV calculation considers a 25-year lifetime for PV and BESS systems. In the life cycle, the cost of the project includes: (1) The cost of PV systems, (2) the cost of BESS systems, (3) the cost of construction, (4) the cost of maintenance and replacement, and (5) the cost of electricity purchased from the grid. The income of the project includes: (1) Income from selling electricity wholesale, and (2) income from participating in FCAS services.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

The NPV calculation is this research applied the following equation:

$$CF_{n=1} = \frac{\left(C_{PV}+C_{BESS}+C_{E_purchase_grid}+C_{Maintenance}+I_{wholesale}+I_{FCAS}+S_{E_consumer}\right)}{(1+R)^{(n-1)}}$$
$$CF_{n} = \frac{\left(C_{E_purchase_grid}+C_{Maintenance}+I_{wholesale}+I_{FCAS}+S_{E_consumer}\right)}{(1+R)^{(n-1)}} \quad (6)$$
$$NPV = \sum_{n=1}^{25} CF_n$$

where, CF_n is the present value of annual cashflow at year n, C is the cost item, I is the income item, $S_{E_consumer}$ is the saving in expenditure on electricity by offsetting users' demand, and R is the discount rate.

Figure 9 shows the histogram of the VPPs' economic performance in each community measured by 25 years NPV. The X-axis has a range from AUD −7 to 10 million with an interval of AUD 1 million. The Y-axis shows the count of observations within each interval.

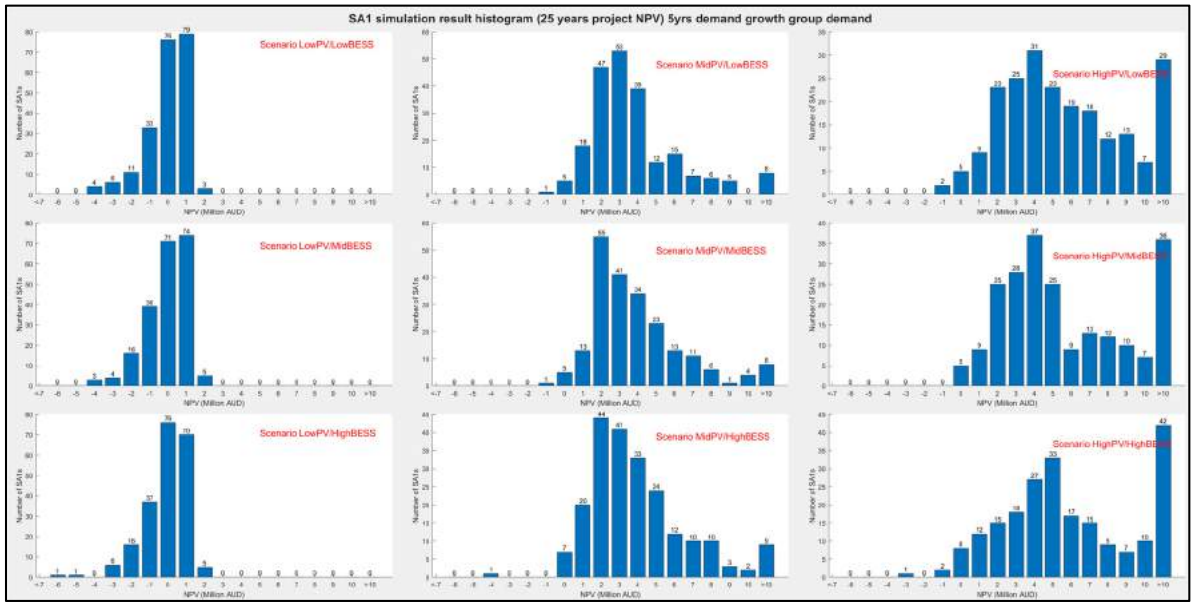

Figure 9. Histogram plots of SA1 simulation results for 25 years NPV.

It was found that the financial performance of VPP largely relies on the capacity of renewable generators and storage systems. When the capacity remains at the current level, the forecasted net present value (NPV) for investing in community-level VPP will be low. The simulation results on the 25 years project NPV indicate that with current PV coverage, most of the SA1s have low NPV or negative NPV values and the lowest NPV is around AUD −5 to −4 million. In the current scenario, around 34–35% of the SA1s have positive NPV values. This indicates that the investment in VPP with current installed PV capacity will have a relatively low expected financial payback.

When the PV coverage increases to medium or high level, the NPV among SA1s shows an increasing pattern, with over 88% of the SA1s populated above AUD 1 million in the 5-year scenario. The percentage grows up to above 90% of the SA1s with a higher NPV than AUD 1 million in the 10-year scenario. Increasing PV capacity will have a positive impact on the VPP's NPV among the SA1s. However, the increase in BESS capacity can have a double-sided effect on the project NPV. For example, if an SA1 community already has a higher estimated profit (above AUD 10 million 25-year NPV), extra BESS capacity will be more likely to further increase the profit level. On the contrary, if an SA1 community has an estimated profit of less than AUD 1 million, the extra BESS capacity that incurs more initial cost and maintenance cost will have a higher chance of reducing the exiting profit.

In summary, the economic payback and project value of the future VPP deployment largely rely on the capacity of PV and BESS system. Higher PV and BESS system capacity

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

gives VPP greater capability in demand offset and energy trading. It can also be found that the high BESS capacity can sometimes reduce project economic feasibility, which may be due to the high capital cost and maintenance cost of the BESS system.

4.3. Economic Benefits of VPP for Communities and End-Users

Based on the calculation of the NPV, this research also provides an estimation of the electricity retail price which can fully offset the cost of the VPP. The adjusted electricity was calculated using the ratio of the users' net demand after the demand offset action of VPP and the 25-year NPV in each SA1, as shown in the following equations:

$$\begin{aligned} CF'_{n=1} &= \frac{\left(C_{PV}+C_{BESS}+C_{E_purchase_grid}+C_{Maintenance}+I_{wholesale}+I_{FCAS}\right)}{(1+R)^{(n-1)}} \\ CF'_{n} &= \frac{\left(C_{E_purchase_grid}+C_{Maintenance}+I_{wholesale}+I_{FCAS}\right)}{(1+R)^{(n-1)}} \\ NPV' &= \sum_{n=1}^{25} CF'_{n} \\ P_{adjusted} &= \frac{\sum_{n=1}^{25} \left(E_{Total}-E_{VPP_User}\right) \Big/ (1+R)^{(n-1)}}{NPV'} \end{aligned} \tag{7}$$

where E_{Total} is the total demand in each SA1 and E_{VPP_User} is the user demand offset by VPP.

Figure 10 is the histogram plots of the simulation results for the adjusted electricity price with VPP operating under each scenario. The X-axis has a range from 0 to 0.1 AUD/kWh with an interval of 0.01 AUD/kWh. The Y-axis shows the count of observations (i.e., the number of SA1 communities) falling into certain intervals.

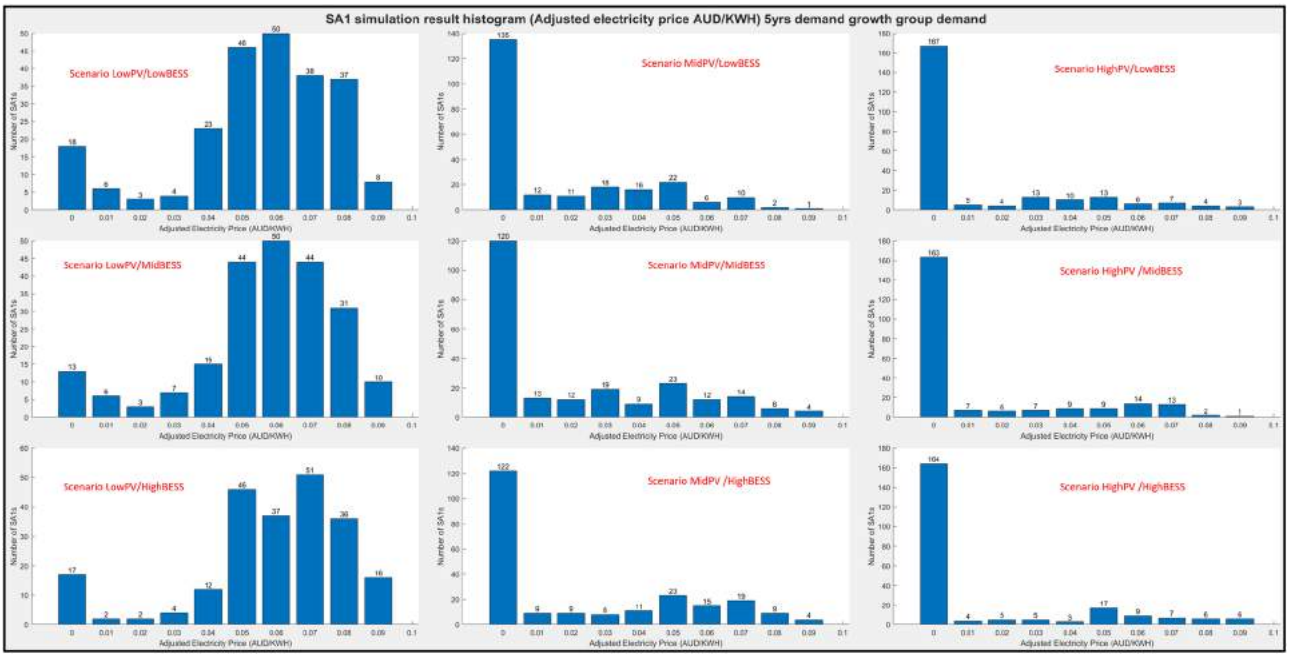

Figure 10. Histogram plots of SA1 simulation results for adjusted electricity price.

The resulting histogram plots are shown in Figure 10. It can be found that VPP's economic performance has a strong impact on reducing the electricity cost for the local communities, even with the current PV installation capacity. Most of the SA1s with current PV capacity and low BESS capacity have reduced electricity price ranging from 0.05 to 0.08 AUD/kWh, while over 50% of the SA1s have an electricity price of less than AUD 0.01. This illustrates a significant reduction compared to the Default Offer electricity price (ranging from 0.1297 to 0.3091 AUD/kWh, excluding the service charge) provided by the Essential Services Commission (ESC) of Victoria [58]. This demonstrates that the

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

VPP has significant capacity in reducing the users' electricity expenditure with different demand profiles.

The results from the adjusted electricity price indicate that VPPs offer significant benefits to end-users, even at the current level of renewable energy and BESS coverage. Comparing the first column of Figures 9 and 10, it can be seen that despite the NPVs of investment being suboptimal at low-PV and BESS coverage levels, end-users would still benefit from much lower electricity prices by using VPPs. Therefore, it is recommended that government bodies and potential investors take into account the positive impact on end-users when considering VPP deployment. The successful implementation of VPPs largely depends on the increase in distributed renewable energy and storage capacity. Since a large portion of the procurement for such distributed generators comes from prosumers or households, it is crucial to demonstrate the direct benefits of participating in VPPs to end-users, prosumers, and the wider community.

4.4. Consumption Efficiency Measured by Load Factor

The load factor is an essential indicator for assessing the effects of load on the power grid. As a distributed generator network, VPP has a significant impact on grid stability. The load factor is defined as the ratio of the average load over time to the peak load over time. The electricity infrastructure is built to sustain peak loads rather than normal loads. When the load factor in a user cluster is higher, it signifies that the average load of the users is close to the peak load, indicating that the energy infrastructure in this cluster is more efficient. In contrast, if the load factor is low, it suggests that the consumers' electricity consumption is substantially lower than the peak demand that the electricity network is designed to meet most of the time. As a result, a higher load factor indicates that the electricity network is more efficient, whereas a lower load factor indicates that the network is less efficient, and the network requires more ancillary service capacity to mitigate imbalanced frequency or voltage when demand is much lower than the designed capacity.

This section provides an assessment of the VPP model's impact on the grid's consumption efficiency using load factor as an indicator. The load factor in this study was calculated using the following equation:

$$F_L = \frac{\overline{\sum_n E_{\frac{h}{n}}}}{\max\left(E_{\frac{h}{n}}\right)} \times 100\% \tag{8}$$

where F_L is the load factor as a percentage and $E_{\frac{h}{n}}$ is the hourly user demand in a year.

In this study, a comparison was made between the original load factor and the load factor under VPP control. The original load factor was calculated using the current demand data in each SA1, and a histogram plot was created (Figure 11) to show the distribution of the load factors among the SA1s. The X-axis in Figure 11 represents the range of load factor from 50 to 80% with an interval of 10%, while the Y-axis shows the count of observations that belong to each interval. The figure shows that, of the 235 SA1s, over 50% have load factors of around 60–65% and approximately 30 SA1s have load factors ranging from 65% to 80%. Over one quarter of the SA1s have load factors below 60%.

The load factor results for VPP-controlled scenarios are shown in the histogram (Figure 12). Compared with the original load factor histograms in Figure 11, the histograms of low-PV scenarios in Figure 12 show a significant decrease in the distribution pattern, with over 50% of the SA1s having lower load factors than 55%. This indicates that, when applying the VPP system at current PV coverage level, the VPP will have a negative impact on the efficiency and stability of Bendigo's electricity network. The reason is that PV has a higher output during the daytime while the users do not make their peak demand. However, the PV output is not high enough to last in the system until the peak demand. The consequence is that the PV output only reduces the average demand while the peak demand cannot be mitigated. As a result, the load factor becomes higher than in the situation without PV.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

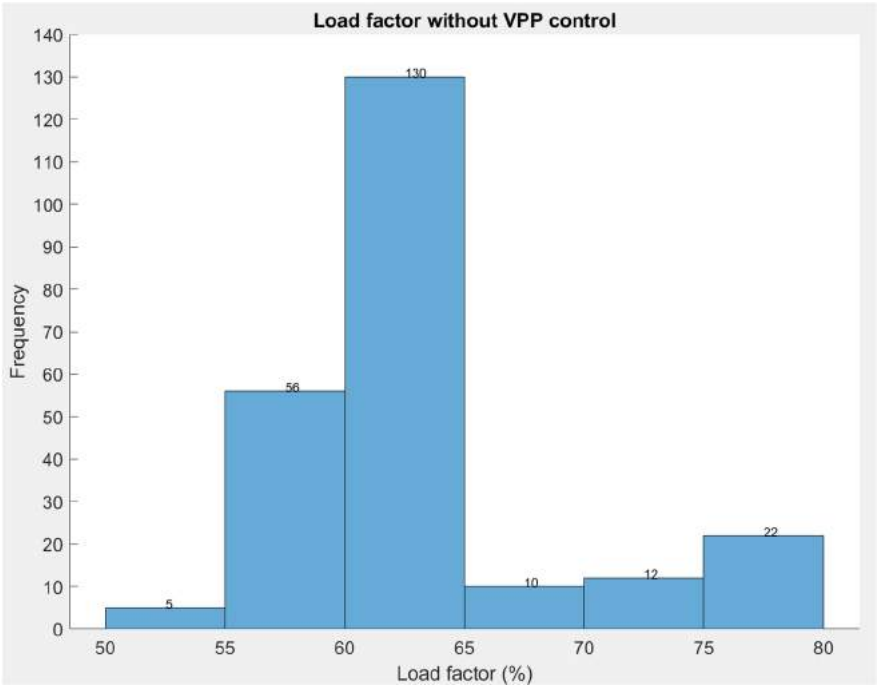

Figure 11. Histogram of SA1s' original load factors without VPP control.

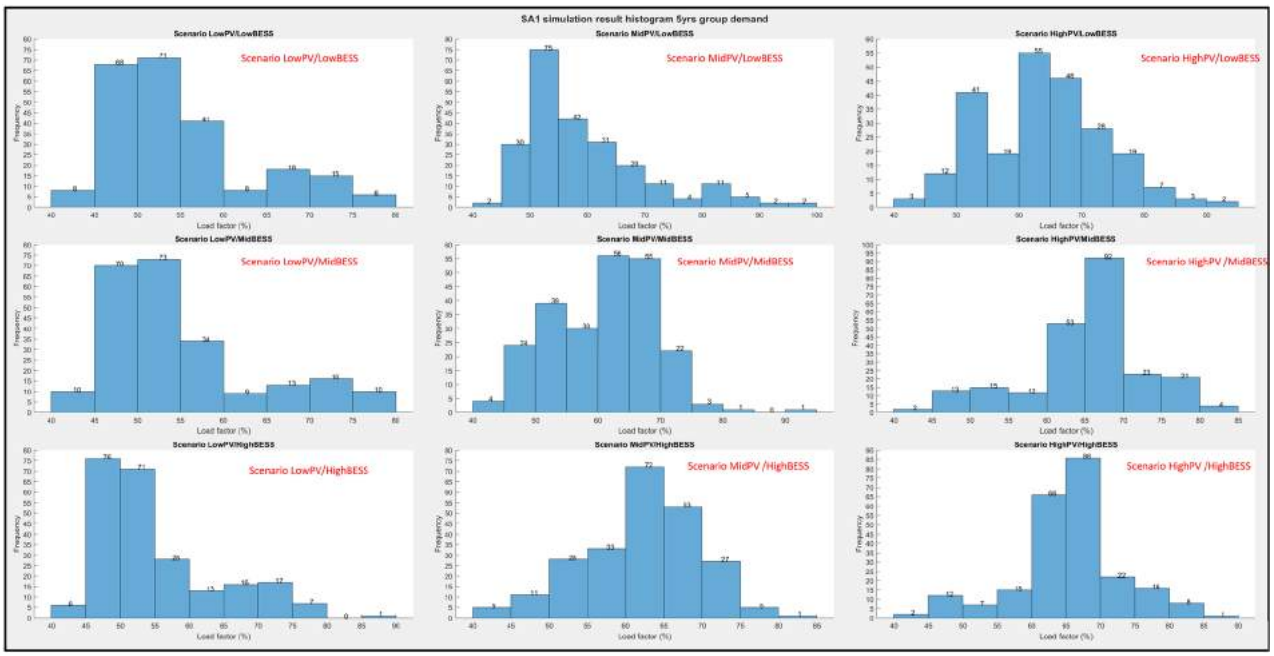

Figure 12. Histogram plots of SA1 simulation results for load factor (%).

The load factor situation is improved as the PV coverage level increases. As Figure 12 shows, in scenarios with high PV coverage and medium–high BESS scenarios, less than 25% of the SA1s have load factors lower than 60%. Furthermore, the BESS capacity shows its benefits in the medium–high PV coverage scenarios, where the scenarios with higher BESS capacity have more SA1s located in the load factor range of 65–75% compared to the scenarios with low BESS capacity.

In summary, the results of load factors presented in Section 4.4 demonstrate that there is a significant impact on the public electricity network in terms of consumption efficiency when PV and BESS coverage are low. The current renewable and storage capacity in the

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

sample communities are not sufficient to effectively offset the peak load among users, resulting in a reduced load factor. This could cause unexpected frequency and voltage turbulence during peak hours, which should be a concern for local network distributors. Increasing the PV and BESS capacity can significantly improve the load factor of most sample communities. However, approximately 10–20 communities experience a drop in load factors even with medium–high PV and BESS coverage. This suggests that VPP may not be a suitable option for these communities from the perspective of grid stability. It is important to consider the balance between the deployment of VPPs and the stability of the public electricity network when planning future investments and policies.

5. Conclusions and Further Research

This paper reports the results of a case study of an implementation of community-focused VPP system in an Australian city. The aim of this study is to investigate the VPP's benefits and risks for end-users and local communities. In this study, a novel VPP model with an RL-based control mechanism is introduced which is capable of operating under various demand and supply profiles within each SA1 community. Geospatial mapping and data mining approaches were utilised to capture the local renewable resources and reconstruct the demand patterns for community-based user clusters. Based on the simulation results, the data analysis provides an overview of the VPP's performance in terms of carbon emission reduction, project economic performance, electricity cost benefits for end-users and communities, and the impacts on the grid consumption efficiency.

From the investment perspective, it was found that at current PV coverage level, the implementation of VPP is not a feasible option due to the risks of low economic value, and relatively poor performance in carbon emission reduction. Nevertheless, analysis of the PV and BESS growth scenarios proves that the VPP has great potential to support the future growth of the city's renewable energy system and unlock the distributed system's values among the communities.

Ideally, with an increase in PV rooftop coverage to 25%, over 50% of the SA1 communities will have a significant reduction in carbon emissions. When the PV coverage further increases to 50% of rooftop are, over 70% of the SA1 communities will reduce the carbon emissions by half. The increasing BESS capacity has the effect of maintaining carbon emission reduction against demand growth. Compared with the scenario groups with low BESS capacity, those with mid to high systems capacity will maintain a higher carbon emission reduction rate even as the electricity consumption continues to grow.

For end-users, VPPs have great capacity in reducing the user's expenditure on electricity in all the scenarios when the adjusted electricity price lower than the Default Offer as provided by the Victoria Essential Service Commission.

The analysis of load factor indicated that with current levels of renewable energy penetration, VPPs tend to have a negative impact on the local electricity network that will lower the consumption efficiency. It is a result of the insufficient PV and BESS capacity, which reduces the average load but fails to significantly reduce the peak load. The alternative scenarios suggested that, with increasing PV and BESS capacity, VPP is capable of improving the load factors compared to the default situation.

Due to the limitations in the data collection, this research does not consider the detailed VPP operation from an electrical engineering perspective. The interaction among VPPs operating in different communities are not considered as this requires single line diagrams of the supply, distribution, and transmission network. The operating voltage and frequency of the VPPs are not considered in this study, as they require further data input and modelling of the grid-connected inverters and the feeder network. It is recommended that future research may further expand the scope of research to include detailed simulation of VPPs to include more aspects of electricity network impact factors such as voltage control and frequency regulation. It is recommended that future studies may considerably expand VPP modelling and functionalities, for example, by integrating a game-theory-based bidding system in the market end of the VPP system model.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

To sum up, this research validates the VPP benefits for end-users and the communities in terms of reducing carbon emissions and reducing electricity costs. However, the financial viability and the grid impacts of VPP projects largely depend on the availability and capacity of the renewable energy generators and storage systems.

Economic, environmental and energy analysis of the utilization of renewable energy based on Analytic Hierarchy Process: a case study

Salam Ollah Mohammadi-Aylar, Morteza Almassi* and Hossein Bakhoda
Department of Agricultural Mechanization, Science and Research Branch, Islamic Azad University, 1477893855 Tehran, Iran

Abstract

Due to the growing reduction of fossil fuels and, on the other hand, the emission of pollution due to the use of these fuels, renewable energy is a very good alternative to produce the required energy. In the meantime, wind and solar energy are very important due to simple technology and production of energy with high capacities. To make the best use of renewable energy, the first step is to measure the potential of the studied areas using the analytic hierarchy process method. To do this, economically influential variables (investment, maintenance costs, energy costs, revenue, rate of return on investment) and environmental variables (global impact (greenhouse gases), regional pollution, health) for utilization of renewable energy (solar, wind, biomass) were studied in eight cities of Ardabil province. The combined system of photovoltaic cell with wind turbine in Ardabil city makes it the most prone area in the province with a return on investment of 2.61 yr. The amount of energy produced for this region is 47944 kW hr/yr.

Keywords: economic analysis; environmental analysis; sustainable development; renewable energy

1 INTRODUCTION

Due to the reduction of fossil fuels and the increase of pollution caused by fossil fuels, the use of alternative energy has increased day by day [1, 2]. In order to use renewable energy, which can be the best alternative to fossil fuels, factors must be considered. The main factors in the use of renewable energy are environmental, economic and social factors [3–5]. The development of renewable energy helps to achieve the goals of economic, social and environmental development, which is one of the key factors in achieving sustainable development in any country [6–9]. It is imperative to use new energy sources instead of fossil fuels today. Today, new energies are rapidly expanding and penetrating and neglect will be irreparable. Solar, wind, biogas and geothermal energy are the main sources of clean energy [10–13]. The access of developing countries to new types of energy sources is essential for their economic development. Due to the lack of access to renewable energy at all times of the year, the use of hybrid systems in this technology is of great importance. Therefore, in designing energy systems based on renewable energy, two or more sources such as sun, wind and biogas should be used [14–16].

Thus far, many researches have been conducted in relation to the concurrent electrical energy with the renewable energy considering smart grid using HOMER software [14–16]. A majority of countries including Iran [17], Pakistan [18], Iraq [19], China [20], India [21], Australia [22] and USA [23] have fulfilled studies on utilization of smart grid based on renewable energies. In other researches, in order to justify the utilization of renewable energies, an analysis of the economic and environmental factors was conducted [24–26]. Some of the researches that considered the utilization of renewable energy can be seen in Table 1.

Decisions about evaluation of the most stable energy resource are significant and complicated. Due to the difficulties of multi-dimensional decision-making, using of analysis of multi-criteria decision-making is essentially appropriate and useful. Therefore, this decision-making problem is promoted from economic and environmental perspective. The aim of this study is the determination of opportunities of renewable energy utilization regarding bio-environmental elements and economic aiming supplement of maximum of required load using analytic hierarchy process method.

2 MATERIALS AND METHODOLOGY

First, the status of potential use of renewable energy for the regions of Ardabil province is determined. Based on the existing potential, the ability to convert to various renewable energies is determined and then the influencing factors are examined. And based on that, the priority of energy utilization is determined. The influential economic factors include investment, maintenance cost, energy cost, income and rate of return on investment. The influential environmental factors include global impact (greenhouse gases), regional pollution and health.

In this research, the possibility of access to various energies in Ardabil province is investigated to be able to take effective measures based on it within the framework for an appropriate strategic plan for the development of new energies. In the long run, prioritization is determined and all economic and environmental factors are feasible and formulated in the form of strategic studies during the necessary researches.

2.1 Geographical characteristics of the study area

The cities of Ardabil province that were studied are listed in Table 2.

2.2 Investigation of wind in the study area

First, wind potential measurement of the eight cities in Ardabil province that were studied was determined based on the results obtained from wind power density. In order to calculate the wind power density, the air density of the area must be determined first. To calculate the air density of the region, indicators such as temperature and humidity of the region must be specified. In this research, information about the temperature and humidity of the cities has been obtained from the General Meteorological Department of Ardabil province. Figure 1 shows the intensity of winds in different cities.

2.3 Examine the intensity of solar radiation in the study area

In this phase of the research, first the required information such as geographical coordinates of the studied cities, air filtration coefficient and the intensity of solar energy radiation were obtained. Then, the average traditional energy solar diagram of the cities of Ardabil province was obtained using HOMER software. Tables and graphs of average solar radiation during the year in the cities of Ardabil province have been determined through HOMER software and are given in Figure 2.

The present work used solar cell and wind turbine to design a hybrid system. Equations governing the function of these devices are presented in Eqs. 1 and 2, respectively [27–30]:

$$P_{pv} = Y_{pv} \times f_{pv} \times \frac{\overline{H_T}}{\overline{H_{T,STC}}} \tag{1}$$

$$P_{WTG} = \frac{\rho}{\rho_0} \times P_{WTG.STP} \tag{2}$$

In the optimization phase of this software, the planned designs are fully examined for a maximum energy and cost reduction [23]. Economic calculations are carried out based on total net present cost (NPC) and load cost of energy (LCOE) parameters [22, 23], with the most optimum system having the least total NPC.

$$NPC = \frac{C_{ann,total}}{\frac{i\,(1+i)^N}{(1+i)^N-1}} \tag{3}$$

$$LCOE = \frac{C_{ann,total}}{E_{Load\ served}} \tag{4}$$

Information on equipment price, size and other design specifications of the renewable hybrid system is indicated in Table 3.

In order to be able to economically analyze renewable energy systems, a certain amount of electrical charge must be considered

3 RESULTS

3.1 Economic analysis

In economic analysis, HOMER software is weighed based on the amount of electricity generated. In weighing the economic analysis of operation, because the rate of return on investment is similar, we determine the weight coefficient based on the amount of electricity generated. The highest amount of electricity generated has the highest weight factor and other cities also calculate the highest weight factor. The results of economic analysis are given in Table 4 . The amount of electricity generated by considering renewable wind and solar energy sources separately by city and also the amount of production of each of these sources can be seen in Figure 6.

Based on Table 4, the investment cost and return on investment, as well as the cost price per unit of electricity generation in the area, can be seen. It can be concluded that the lowest investment cost is related to Meshginshahr. For this region,

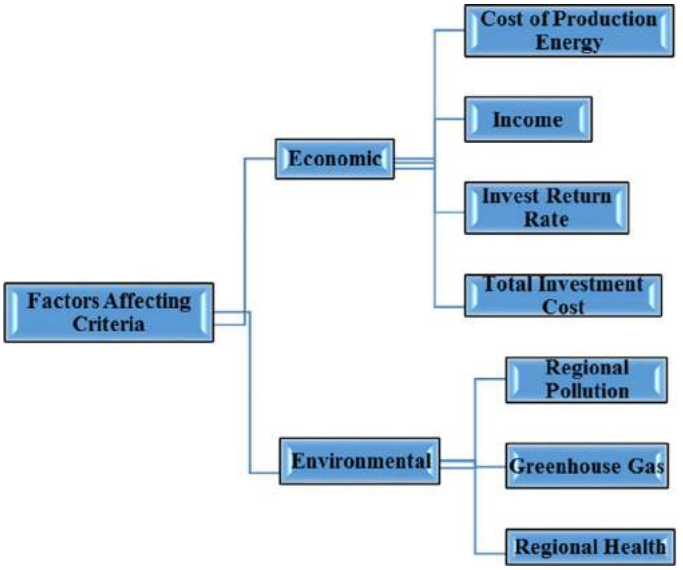

Figure 5. *Factors affecting renewable energy under study.*

the price of each energy unit is $1.41 per kW and the return of investment is 3.41 yrs.

As can be observed in Figure 6, the highest production of the studied system is related to Ardabil city, which is 47944 kW h/yr. From this amount, 30362 kW h/yr is related to power generation by wind turbine and 17582 kW h/yr is related to power generation from photovoltaic cells.

3.2 Environmental analysis

According to the previous information and using the economic analysis tables in the previous part of this research, we multiply the amount of electricity produced by solar and renewable wind energy by the amount of pollution in the table above to determine the amount of pollution that prevents the use of renewable energy. The results of the environmental analysis are given in Table 5.

According to Table 5, the lowest level of non-pollution related to CO is related to the city of Bilesvar with a value of 11.26 gr/kw h. The lowest amount of non-pollution caused by CO2 is related to the production capacity of photovoltaic cells in Bilesvar city with the amount of 9.997 Ton/kW h.

4 CONCLUSION

The potential assessment section based on the results obtained from the research on wind energy in Namin city was first with a wind rate of 5.78 m/s. The power of this wind is 159.15 w/m^2. The solar energy of Parsabad and Meshgin Shahr was in the first priority with the radiation intensity of 3,449 kW h/m^2/yr in both cities.

According to the potential table in Ardabil province in terms of wind power density, which was calculated based on parameters such as air density, temperature, humidity and other parameters,

Priority 1	Priority 2	Priority 3	Priority 4	Priority 5	Priority 6	Priority 7	Priority 8
Khalkhal	Germi	Ardabil	Meshgin Shahr	Namin	Parsabad	Bilehsavar	Sarein

Namin city area was recognized as the most potential area for installing wind turbines. It is recommended for policy and investment in the field of wind energy in Namin city, Ardabil province. In the case of solar energy, Meshgin Shahr and Parsabad are in investment priority.

In economic analysis, the use of solar energy in Ardabil was the first investment priority. Meshgin Shahr wind energy was in the first priority and other cities were in the next priority with a small difference. Based on the results obtained from the environmental analysis of renewable energy in Ardabil province, the first priority is Khalkhal and the last priority is Sarein.

Energetic, environmental and economic aspects of a hybrid renewable energy system: a case study

Ersin Akyuz[1], Zuhal Oktay[1*] and Ibrahim Dincer[2]

[1]Mechanical Engineering Department, Faculty of Engineering, Balikesir University, 10110 Balikesir, Turkey; [2]Faculty of Engineering and Applied Science, University of Ontario Institute of Technology (UOIT), 2000 Simcoe St. N., Oshawa, ON, Canada L1H 7K4

Abstract

In this study, the solar irradiation and wind speed data of Balikesir in Turkey are analyzed to assess the techno-economic viability and environmental performance of a hybrid power system. Energy is estimated for a typical commercial poultry house, and a system is then designed to satisfy the load demand. As hybrid Optimization Model for Electric Renewable (HOMER) software is used for the simulation of four respective cases: Diesel only, photovoltaic (PV)–diesel–battery, wind–diesel–battery and photovoltaic–wind–diesel–battery. We also evaluate the cost, environmental advantages and benefit of the demand-side management (DSM) when renewable hybrid energy options are applied to the poultry farming. By implementing light control system and high-efficiency fans (with about 20% efficiency increase), annual electricity consumptions can be reduced by 15% with DSM. When DSM was applied to the cost of energy, certain parameters including unmet electric load, excess electricity and greenhouse gas emissions are calculated for each case. Greenhouse gas emissions are also investigated for the hybrid energy system (by integrating PV and wind turbine only into diesel system). The hybrid system thus reduces CO_2 emissions from 21.8 to 10 t, particulate matter (PM) from 4.1 to 1.9 kg, NO_x from 0.421 to 0.221 t. A break-even analysis is performed to decide the optimum distance where the hybrid energy system is more economical than the extension of the transmission line. Consequently, the results indicate that installation of the hybrid energy system is more economical than the conventional electricity network when the distance is more than 3.21 and 3.13 km for PV–wind–diesel–battery and wind–diesel–battery, respectively.

1 INTRODUCTION

Implementing sustainable energy strategies is one of the most important aspects for a sustainable world. Future energy policies and strategies should put more emphasis on the development of potential energy sources, which should form the base of future global energy structure. Agriculture's role in energy consumption is well known. Farm-based energy production—biofuels and wind-generated electricity—has grown rapidly in recent years, but still remains small relative to the total national energy needs. Energy obviously plays an important role in poultry production [1]. Therefore, the present study investigates the technical and economic potentials of renewable hybrid energy options for poultry farms in Balikesir, Turkey. The poultry sector is one of the most important areas of the food industry in Turkey. At present, there are ~12 700 broiler companies in this sector and the majority of broiler chicken production is carried out by integrated companies [2]. According to Food and Agriculture Organization of the United Nations (FAO) production statistics, Turkey occupied the 19th rank in the world poultry production. Total poultry meat production reached to 1 063 795 t in 2005. In this regard, poultry production has a great potential in the Balikesir area, which occupies the second rank in poultry production and third rank in total agricultural production in Turkey. In addition, there are about 3000 broiler companies in the Balikesir area [3]. Therefore, this study is expected to serve as a kind of guidance to the respective poultry sector with respect to how efficiently

International Journal of Low-Carbon Technologies 2011, 6, 44–54

and effectively energy can be used and how effectively emissions can be minimized. It is also expected to provide better demand-side management (DSM) strategies.

In the literature, one of the very first studies was conducted by Ref. [4] on the potential of solar electric applications for Delaware's poultry farms in April 2005 and on the feasibility of photovoltaic (PV) system used in poultry farms. The researchers carried out a feasibility study using a simulation model approach and testing alternative scenarios and cost conditions. Their study shows that solar energy is economical for the state's producers under certain policy scenarios. Their results indicate that the electricity needs of an economical PV system used in a typical Delaware poultry house was 1.5 kW. The environmental impact study demonstrated that the 1.5 kW PV system avoided 112 t of CO_2 emissions during its lifetime as well as reducing 1.8 t of sulfur dioxide (SO_x) and 0.4 t of nitrogen oxides (NO_x) [4]. Bazen and Brown [5] analyzed broiler production in five different regions in Tennessee, which accounted for about 46% of total production in the state. They investigated not only the economic feasibility of solar PV energy integration, but also the impact of alternative energy programs and other factors in several solar regions within Tennessee's poultry industry.

The utilization of PV–wind–diesel hybrid energy sources can significantly reduce the system fuel costs. Also, it has positive effects on the system reliability [6]. In the past, high investment rate was an important barrier for consumers. PV price has dropped from US$25 to 3.5 per W in the past 30 years [5]. Several authors have discussed the energy requirements of PV solar energy conversion systems and their energy pay-back-time [7–9]. Wichert *et al.* [10] published an evaluation of technical and economic characteristics of hybrid power systems, and outlined the expected future directions for the development of hybrids. Hybrids are in a more favorable position when the cost of diesel fuel transportation is incorporated in the analysis. Sizes of many hybrid systems have been studied and optimized by the economic analysis based on life-cycle cost (LCC) and energy cost [11–13]. Studying cost and environmental impacts of such hybrid PV–wind–diesel–battery generator systems on other systems is of great importance to diminish global warming problem. Baring [14] outlines the foundations for analysis and design of some hybrid power systems.

One of the purposes of this study is to evaluate the cost, environmental advantages and the benefits of the DSM when renewable hybrid energy options are used in poultry farming. This concept has been applied to renewable energy (RE) electrification system in order to reduce the peak energy demand and also to have an arrangement where poultry energy operations can be matched to the high potential period of electrical energy produced from hybrid system during the day [15]. To achieve a cost-effective electrical system, components of the system must be chosen carefully and the system must be operated in a way to minimize costs. Generally, more efficient electrical components have higher initial cost, which should be weighted against the future savings to be realized in terms of reduced energy charges [16]. For RE systems, DSM becomes beneficial to strengthen their use. DSM has been used to smooth the daily peaks and fill valleys in the load profile to make the most efficient use of energy resources [e.g. 17,18].

2 METHODOLOGY

2.1 Input parameters for simulation

In the simulations, the actual data including the hourly global solar irradiations on tilted plane (39°) for 2003 and average hourly wind speed were collected from the Department of Turkish State Meteorological Services in Balikesir airport and employed for calculations as given in Table 1. Solar irradiation level is higher in the summer months. The monthly solar global radiation values range from 1.8 to 7.49 kW h/m^2 between December and July. On the other hand, the annual average daily solar global radiation level is determined as 4.48 kW h/m^2. Average monthly wind speed at 25 m varies from 2.80 to 5.83 m/s.

2.2 Description of the poultry house

In general, the design of a hybrid energy system is site-specific and depends upon the available resources and the load profile. For the systems, such as the PV–diesel, wind–diesel and PV–wind–diesel, the design capacity was determined and optimized using the HOMER (Hybrid Optimization Model for Electric Renewable) software program. It was able to test all the proportions regarding the cost of energy (COE) and determine the minimum COE as the optimal design capacity. Hourly wind speed, solar radiation, load profile, and component price were used as input data of the HOMER software.

Energy needs were determined in terms of all actual electrical equipments used in the farmhouse. There was a generator with capacity of 10 kW in the facility. Therefore, no change was made for the backup diesel generator capacity in the simulation for Case 1. Simulations were carried out, and have been applied to design a stand-alone hybrid power system in order to generate energy for a poultry house in Balikesir (39°30′N–28°1′E). The farmhouse is considered to have an average

Table 1. *Monthly average wind speed and global irradiation values.*

	January	February	March	April	May	June	July	August	September	October	November	December

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

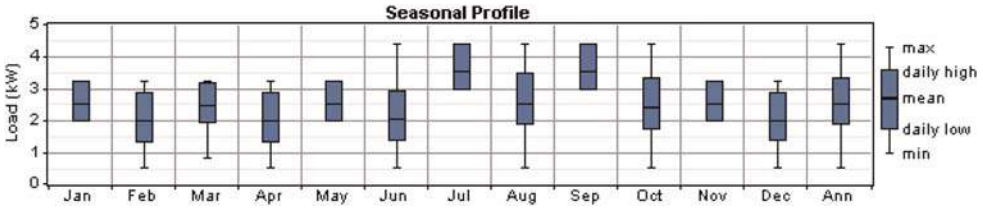

Figure 1. *Load profile for poultry house (without-DSM).*

energy consumption of about 60 kW h per day, with a peak demand of 4.37 kW and mean demand of 2.5 kW. The daily load demand is given in Figure 1. A DSM was considered to make a more efficient design. When DSM was considered, the generator capacity was chosen as 5 kW as being close enough to the peak load. Depending on this consideration, a lower capacity generator could obviously be selected.

A number of broiler companies were interviewed to assess their energy needs in order to estimate the electricity demand. Energy plays an important role in broiler production. In a typical commercial poultry house, energy is used for heating system circulation pumps, ventilation and lighting, and feed lines motors. In winter months, 45% of this potential electric load is derived from ventilation, 25% from lighting, 10% from administrations home, 10% from water pump and 8% from feed lines, etc. However, in summer months, 60% of this potential electric load results from ventilation, 17% from lighting, 8% from administration's homes, 9% from water pumps and 6% from feed lines. Electrical equipment used in the poultry house are presented in Table 2. There is a significant difference in load profile between summer and winter seasons. Owing to the high cooling and ventilation needs, the load demand in broiler companies is higher in summer, while average daily electricity consumptions annually are of 21893 kW h. Temperature and humidity levels in poultry houses are controlled automatically. Temperature of the poultry houses varies from 33°C, in the first week, to 25°C, in the seventh week, as determined by the grower's contract. Most of the poultry houses have 23 000 broilers in the home area of 10 000 m^2 as an average size in Balikesir. There are six growing periods in a year for broilers and each growing period is about 45 days, and 15 days are used for cleaning and preparation.

2.3 Energy management for poultry house

DSM is used in the areas where RE electrification system is supplied to the utilities. DSM has certain benefits to strengthen the RE system. Implementation of energy efficiency measures is projected to reduce the total site load by 18505 kW h/year, about 15% of the present value. In Table 3, two different types of 24-h load profile were identified for poultry farming in Balikesir:

(i) The conventional applications are low energy efficient and not optimized for energy efficiency (without DSM). The daily consumptions are 60 kW h/day, peak load is 4.37 kW and average load is 2.5 kW (Case 1).
(ii) Systems with DSM 'high efficiency' is rather scarce on the market and has a higher price than conventional appliances. The daily consumption is 51 kW h/day, peak load and average load are 3.31 and 2.11 kW, respectively (Case 2).

Table 2. *Electrical equipments which are used in poultry house.*

Device	Number	Voltage	Power (W)	Total power (W)
0.91 m Sidewall fans	6	380	300	1800
1.22 m Tunnel fans	4	380	1000	4000
Lighting	50	220	9	450
Water pump	1	380	1000	1000
Feed line motors	2	380	500	1000
Total (W)				8250

For Case 2, fans are replaced with highly efficient ones and used for the ventilation and optimization of lighting. For this case, parameters like the peak load demand, average daily load and annual electricity consumptions are reduced by 24, 15 and 15%, respectively, when DSM is applied. Optimization of ventilation system means the substitution of the existing fan technology with a more efficient one. At present, asynchronous motors are in use and an even more efficient drive is an electronically commutating (brushless) DC motor. For example, a standard 1.22 m box fan would have an average efficiency of 28.8 m^3/W h, while a high efficiency 1.22 m box fan would move 33.82 m^3/h W or more than a 20% of increase in efficiency [18].

These case systems were modeled for an average commercial poultry house, and accordingly, simulations were carried out. Equipment options included lighting control and highly efficient fans. Lighting and ventilation are potentially the largest-end uses when achieving the recommended lighting and ventilation levels. Results show that peak demand of the poultry farm house reduced from 4.37 to 3.1 kW. In addition, the cost of electricity for hybrid system also decreased.

3 ANALYSIS

3.1 Simulated hybrid energy system

A hybrid energy system, consisting of two or more energy systems, an energy storage system, power conditioning

equipment and a controller, is the most appropriate energy producer for isolated communities, especially in remote areas. There are generally two accepted hybrid energy system configurations, namely: (a) systems mainly based on diesel generators with RE used for reduction of the fuel consumption; (b) systems relying on the RE source with a diesel generator used as a back-up supply for the extended periods of low RE input or high load demand.

Some software tools that assess the performance of an RE system for system configurations are SIRENE, RAPSIM and SEU-ARES. Most of these software tools simulate the predefined hybrid RE system based on a mathematical description of the component characteristic operation and system energy flow, and often, financial costing of the system configuration. These packages are valuable to assess certain hybrid system designs and enable viewing the effects of changing component sizes and settings manually. Better system performance and lowered costs could be achieved with many of these designs if the system configurations could be optimized. HYBRID2, developed by NREL in 1993, is simulation software aiming to provide a versatile model for the technical and economical analysis of hybrid system performance. The software INSEL, written at the University of Oldenburg, is a logistic simulation model for RE systems. SIRENE, developed in 1991 by Bezerra *et al.* [19], aims to simulate the electrical network and economic performance of a given type of hybrid system supplying electricity to an isolated grid in order to avoid costly parameter adjustment work during installations [20].

In this study, four systems, namely (i) diesel-only, (ii) PV–diesel–battery, (iii) wind–diesel–battery and (iv) PV–wind–diesel systems, are considered and simulated by HOMER [21] software to assess their techno-economic viability. The HOMER was developed by the National Renewable Energy Laboratory (NREL) in the USA as a potential simulation and optimization tool for RE systems. The HOMER performs three principal tasks: simulation, optimization and sensitivity analysis. In the simulation process, HOMER models the performance of a particular micro power system configuration for each hour of the year to determine its technical feasibility and LCC. In the optimization process, HOMER simulates many different system configurations in search for the one that satisfies the technical constraints at the lowest LCC. In the sensitivity analysis process, it performs multiple optimizations under a range of input assumptions to gauge the effects of uncertainty or changes in the model inputs. The optimization study determines the optimal values of the variables over which the system designer has control, such as the mix of components that make up the system and the size or quantity of each. A sensitivity analysis helps assess the effects of uncertainty or changes in the variables over which the designer has no control, such as the average wind speed or the future fuel price.

PV–wind-generated energy stored in batteries can be retrieved during nights. Use of diesel system with PV–wind–battery reduces battery storage requirements. Hybrid combination of PV–diesel–battery system represents an economically acceptable compromise between the high capital cost of PV autonomous system and high operation and maintenance and fuel cost of generators [22]. The technical data and economic assumptions of PV, Wind, diesel generator unit, DC–AC inverter and batteries are presented in Table 4.

3.2 Economic analysis

The economic analysis involves calculation of the simple payback time (SPBT) for the PV module and calculation of energy payback time (EPBT) for the PV array. In order to calculate the EPBT it is essential to know the energy required in the construction of the PV array (so-called: embodied energy). In this method, the total energy required is the sum of energies required for raw materials and the energy required in the various processes involved to convert the raw materials into the PV array. The embodied energy of a PV system is given by

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Wies *et al.* [23] as:

$$\begin{aligned} \text{kW h}_{\text{emb}} &= 5600\,\text{kW}_{\text{p}} = 33\,600\,\text{kW h} \\ \text{EPBT} &= \frac{\text{kW h}_{\text{emb}}}{E_{\text{pv}}} = \frac{33\,600}{8176} = 4.10\ \text{year} \end{aligned} \tag{1}$$

The SPBT can be calculated using the simple formulation below (Equation (2)), [23,24].

$$\text{SPBT} = \frac{\text{Excess cost of hybrid system}}{\text{Rate of saving}} \tag{2}$$

The SPBTs for the options without DSM hybrid are calculated as 7.9, 5.7 and 12.6 years for PV–wind–diesel–battery, wind–diesel–battery and PV–diesel–battery, respectively. On the other hand, SPBT for the options with DSM hybrid is found as 5.3, 4.7 and 7.3 years for PV–wind–diesel–battery, wind–diesel–battery and PV–diesel–battery, respectively.

The LCC analysis is a tool used to compare the ultimate delivered costs of technologies with different cost structures. Rather than comparing only the initial capital costs or operating costs, LCC analysis seeks to calculate the cost of delivering a service during the whole period of the project. The final cost per kW h is estimated independent of the technology used to deliver the electricity. Levelized energy cost (LEC) can be explained with total present value (TPV), and annual load (AL) kW h, as follows [22]:

$$\begin{aligned} \text{TPV} = {} & \text{Initial cost} + \Sigma\text{O\&M} + \Sigma\text{Replacement} \\ & + \Sigma\text{Fuel cost} \end{aligned} \tag{3}$$

$$\text{LEC} = \frac{\text{TPV} * \text{CRF}}{\text{AL}} \tag{4}$$

where CRF is the capital recovery factor and defined as:

$$\text{CRF} = \frac{(1+R)^N * R}{(1+R)^N - 1} \tag{5}$$

Here, R is of 10% of the net discount rate and N is of 25% of the economic evaluation period.

3.3 Break-even analysis

A break-even distance analysis was carried out for hybrid energy system and extension of transmission line. Break-even distance analysis showed how far the site of the stand-alone energy system should be from the existing utility grid in order to make the system cost-effective compared with using conventional transmission line [25]. The total cost obviously changes according to the length of the transmission line. Such a cost is the sum of the operation cost and investment cost. Operational costs of the grid system are the electricity consumption fee and the maintenance costs. Total cost of extension has two parameters; fixed cost and variable cost as given in Table 5. The capital cost per kilometer is calculated as US$ 40 000, O&M cost as 300 $/km/year, grid power price as 0.17 US$/kW h:

Table 5. *Cost parameters of grid extension for break-even analysis.*

Fixed cost	Pile (2790 kg), Distributor transformer: 31.5 kV, 50 kVA, Transformer platform: PL-250 (700 kg), Current transformer: 75/5 A OG fuses: 36 kV, 2–20 A, Fuse separator: 36 kV–630 A, Ground separator: 36 kV–630 A, Power panel, Electric meter 220/380 V Circuit breaker 3 * 80 A compact
Variablecost	Pile installation, Pile transportation, Wire (110 kg/km), Pile 8–12 (2170 kg)

$$C_{\text{Ex,T}} = C_{\text{i}} + C_{\text{op}} \tag{6}$$

where $C_{\text{Ex,T}}$, C_{i} and C_{op} represent the total cost of extension, initial cost and operation cost, respectively.

The total operation cost of the extended transmission line is given by

$$C_{\text{op,T}} = C_{\text{M,T}} + C_{\text{E,T}} \tag{7}$$

where $C_{\text{op,T}}$, $C_{\text{M,T}}$ and $C_{\text{E,T}}$ represent total operation cost, total maintenance cost and total electric cost, respectively.

As can be seen from Table 6, the result of the break-even analysis shows that the distance was more than 4.7 km for PV–wind–diesel–battery, 4.8 km for wind–diesel–battery and 6.15 km for PV–diesel–battery. Results also were calculated with DSM option; and the distance was found to be more than 3.21 km for PV–wind–diesel–battery, 3.13 km for wind–diesel–battery and 4.11 km for PV–diesel–battery.

3.4 Environmental impact

Increasing concerns over global warming as a potential result of greenhouse gas emissions caused by fossil-fuel-based energy sources have motivated many to do research on cleaner and greener energy options, e.g. PV, and wind systems for various applications. The environmental benefits of integrating hybrid RE in poultry farming are very important in terms of greenhouse gas emissions. The amount of pollutant emissions was calculated and compared with the diesel-only option. The annual pollutant emissions are given for each system in Figure 2. The diesel-only electricity generation mainly depends on fuel. Therefore, the amount of fuel usage and its negative effects on the environment are high. As it is shown in Figure 2, diesel-only system produced 27 997 kW h electric energy and 36.8 t of CO_2, 6.9 kg of PM, 0.812 t of NO_x emission in a year time as a result of diesel fuel usage. Replacing the diesel-only system with 4 kW PV array and 9 kW wind turbine reduces the greenhouse gas emission to 10.8 t for CO_2, 2.02 kg for PM and 0.239 t for NO_x and produces 339 196 kW h of electricity on top of that.

In the diesel-only system for DSM simulation, greenhouse gas emission is reduced to 21.8 t for CO_2, 4.1 kg for PM and 0.421 t for NO_x. Integrating PV and wind turbine with a diesel

only system reduces the greenhouse gas emissions to 10 t for CO_2, 1.9 kg for PM and 0.221 t for NO_x.

4 RESULTS AND DISCUSSION

Both load profiles for poultry house (with/without DSM) were developed and simulated with HOMER in order to evaluate the operational characteristics, namely the annual electrical energy production, excess electricity, renewable fractions. Annual diesel consumption and environmental impact parameters namely carbon emissions were calculated. In addition, a break-even analysis was performed to decide the optimum distance where the hybrid energy system should be more economical than the extension of the transmission line. Moreover, a cost analysis of the hybrid power system and a sensitivity analysis for the effect of diesel price on the COE produced by the hybrid systems were also conducted. At present, the average diesel price in Turkey is 1.45 US$/l. An annual interest rate of 10% and a project lifetime of 25 years were used in the economic calculations. Both percent and annual energy productions of each sources are shown in Figure 3 for both cases. The results of the simulation showed that the PV–wind–battery–diesel system had a total annual electrical energy production of 39 771 kW h. When DSM was applied, PV–wind–diesel–battery annual energy output was reduced to 26 614 kW h.

The variations of solar and wind energy generations do not match with the time distribution of the load demand. As given in Table 6, the PV–wind–diesel–battery hybrid system is suitable for the load profile without DSM in terms of COE, and the wind–diesel–battery is suitable for DSM load profile. This option change is to the reason that the COE depends mostly on fuel consumption. When the four options were compared in terms of fuel consumed rate, PV–wind–diesel–battery option was found as 4120 l/year, which is the lowest value for without the DSM case. Also, for the DSM case, fuel consumed rate of wind–diesel–battery was found to be the lowest. Because of low fuel consume rate, both COE and greenhouse gas emissions (CO_2, PM, NO_x) emitted to atmosphere became lower. In addition, the load profile of system matches the RE generations. PV–wind–diesel–battery system, COE of Case 1 and Case 2 is smaller than PV and wind options. This result can be attributed to the fact that the fuel consumption is lower than the other systems. Also, load profile of system matched with RE generations.

The results of sensitivity analysis are presented for without DSM in Figure 4. As can be seen in this figure, in the sensitivity analysis, seven diesel price values (from 1.45 to 2 US$/l) were

AL (kW h)	21 900	18 505	21 900	18 505	21 900	18 505	21 900	18 505
COE (U$/kW h)	1.039	0.872	1.061	0.855	1.306	1.069	1.76	1.143

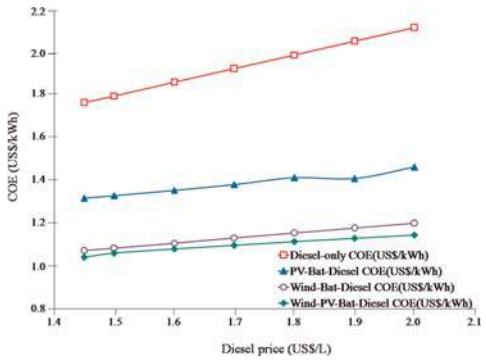

Figure 4. *Effect of diesel fuel price on COE for Case 1.*

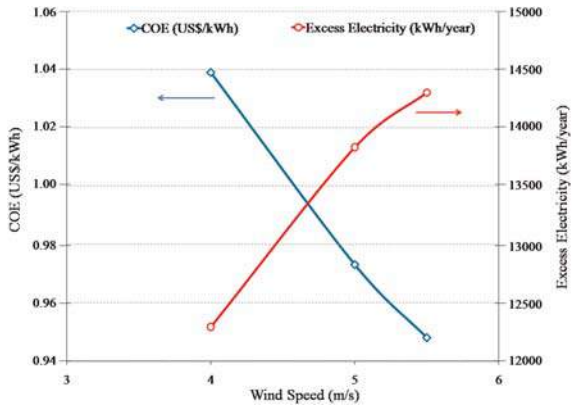

Figure 5. *Effect of varying wind speed on COE and excess electricity of PV–wind–diesel–battery system for Case 1.*

used to calculate the COE energy of each systems. The increase rate is the lowest for PV–wind–diesel–battery option. PV–diesel–battery system and only diesel options are mostly dependent on fuel price. When DSM was applied, COE ranged from US$ 0.872–0.974 for wind–PV–diesel–battery system. As the diesel price increased in sensitivity analysis, fuel cost also increased for both DSM and without DSM cases. Different wind speed and solar irradiation values were used in the sensitivity analysis in order to calculate the COE for various locations around Balikesir. In addition, the effect of wind speed was also investigated and shown in Figure 5. Wind speed values varying between 4 and 5.5 m/s were used as sensitivity variables to calculate the effect of COE and excess electricity produced from system. As can be seen from Table 7, wind–diesel–battery is a suitable case in terms of COE. It is clear in Figure 5 that while COE decreases from US$ 1.039–0.95 for the wind values varying between 4 and 5.5 m/s for Case 1 option, excess electricity increases from 12 187 to 14 350 kW h. If DSM is applied to the system (Case 2), COE decreases from US$ 0.853–0.669 for the wind values varying between 4 and 5.5 m/s and excess electricity needs decrease from 12 829 to 19 180 kW h.

Table 8. *Testing for the reliability of the program results.*

	HOMER	Calculation
Generator output (kW)	9724.4	10 627.6
Wind output (kW))	21 673	21 677.9
Generator fuel (l)	4320	4635
Annual cost ($)	15 858	16 413
COE ($/kW)	0.857	0.887
	Error	3.38%

The simulation results of wind–diesel–battery system for Case 2 are selected to test the reliability/validity of the program. The output power of WS Whisper 500 wind turbine power is fitted with a sixth degree polynomial curve, and wind output power is calculated with a MS Excel program using hourly (8760 h) wind speed data. The amount of time required for diesel generator to work is determined for a farm, the hourly load demand of which is known, and fuel consumption is calculated depending on this value. For economic calculations, the unit prices, 25-year economic life and inflation rates of components used in simulation were taken into account to calculate the annualized cost. Reliability of the program results is shown in Table 8.

5 CONCLUSIONS

This study has examined a hybrid, RE-based power generation system and studied electrical loads of a poultry farm in the Balikesir region for potential replacements to system components and other energy efficiency improvements which will help reduce the peak and overall electrical load at the poultry farm houses.

Four power generation systems have then been simulated. The base system is that of a stand-alone diesel generator. Other alternative systems include a combination of PV and wind as a generation source. The 25-year LCCs associated with each power system was calculated for each case. Besides, break-even distance analysis was carried out for hybrid energy systems and extension of transmission line. The distance, more than 4.7 km for PV–wind–diesel–battery, was found economical. In addition, the distance more than 3.12 km was also economical when DSM was implemented.

At present, RE-based hybrid energy systems may not appear as cost-competitive against conventional fossil-fuel-based stand-alone or grid interfaced power sources. As a result of the need for cleaner energy sources, improvements in alternative energy technologies and increase in fuel price, it is expected that there will be widespread use of various alternative energy sources in the future.

In future studies, it is planned to investigate the simulation models experimentally. In order to reduce the greenhouse gases emission and have the system work more reliably, some fuel cell and small hydro options will also be integrated to the hybrid system. Integration of the hybrid energy system with hydrogen storage, which is system excess energy, will enable the system to work more efficiently.

Green Conversion of Carbon Dioxide and Sustainable Fuel Synthesis

Hosam M. Saleh * and Amal I. Hassan

Radioisotope Department, Nuclear Research Center, Egyptian Atomic Energy Authority, Cairo 11787, Egypt; virtualaml@gmail.com

* Correspondence: hosamsaleh70@yahoo.com or hosam.saleh@eaea.org.eg

Abstract: Carbon capture and use may provide motivation for the global problem of mitigating global warming from substantial industrial emitters. Captured CO_2 may be transformed into a range of products such as methanol as renewable energy sources. Polymers, cement, and heterogeneous catalysts for varying chemical synthesis are examples of commercial goods. Because some of these components may be converted into power, CO_2 is a feedstock and excellent energy transporter. By employing collected CO_2 from the atmosphere as the primary hydrocarbon source, a carbon-neutral fuel may be created. The fuel is subsequently burned, and CO_2 is released into the atmosphere like a byproduct of the combustion process. There is no net carbon dioxide emitted or withdrawn from the environment during this process, hence the name carbon-neutral fuel. In a world with net-zero CO_2 emissions, the anthroposphere will have attained its carbon hold-up capacity in response to a particular global average temperature increase, such as 1.5 °C. As a result, each carbon atom removed from the subsurface (lithosphere) must be returned to it, or it will be expelled into the atmosphere. CO_2 removal technologies, such as biofuels with carbon sequestration and direct air capture, will be required to lower the high CO_2 concentration in the atmosphere if the Paris Agreement's ambitious climate targets are to be realized. In a carbon-neutral scenario, CO_2 consumption with renewable energy is expected to contribute to the displacement of fossil fuels. This article includes a conceptual study and an evaluation of fuel technology that enables a carbon-neutral chemical industry in a net-zero-CO_2-emissions environment. These are based on the use of collected CO_2 as a feedstock in novel chemical processes, along with "green" hydrogen, or on the use of biomass. It will also shed light on innovative methods of green transformation and getting sustainable, environmentally friendly energy.

1. Introduction

Global carbon emissions fell 5% in the first quarter of 2020 compared to the first half of 2019, owing to lower coal consumption (8%), oil (4.5%), and natural gases (2.3 percent). Another paper provided the daily, monthly, and annual rhythms of CO_2 emissions and anticipated an 8.8 percent reduction in CO_2 in the first half of 2020 [1]. The COVID-19 epidemic caused the largest dramatic drop in worldwide CO_2 emissions since World War II [2]. The Worldwide Atmospheric Research anticipated that global human fossil CO_2 emissions in 2020 will be 5.1 percent lower than in 2019, at 36.0 Gt CO_2, barely below the 36.2 Gt CO_2 emission level recorded in 2013 [3]. Global carbon emissions (fossil fuels) per unit of Gross Domestic Product (GDP) decreased in 2019, averaging 0.298 t CO_2/k USD/year, but per capita carbon emissions were steady at 4.93 t CO_2/capita/year, confirming a 15.9 percent increase since 1990 [4].

To minimize the magnitude of global warming, substantial reductions in CO_2 emissions from fossil fuel use are necessary. In view of the steadily increasing interest in

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

preserving the environment and mitigating the consequences of climate change and global warming, hence, great attention is dedicated to finding alternative sustainable methods or eco-friendly economic materials to reduce the use of cement in various fields and consequently reduce the CO_2 emissions accompanying with intensive energy consumed in the cement industry. Various additives have been mixed with cement such as bitumen [5,6], asphaltene [7], glass [8,9], polymers [10–12], nanomaterials [13,14], cement wastes [15,16], bio-waste [17–19] or natural clay [20,21] to improve the material features and minimize the cement incorporation and environmental pollution.

However, carbon-based liquid fuels will continue to be key energy storage media for the foreseeable future [22]. We suggest using solar energy to recycle atmospheric CO_2 into liquid gasoline using a mix of mostly available technologies. The world population hit 7 billion in 2011 and is expected to exceed 9 billion by 2050, according to the United Nations, significantly increasing energy consumption. According to Hubbert's peak theory, oil resources will plummet dramatically during the next 40 years [23]. As a result, the years 2055–2060 may be the last in which oil output reaches zero. Furthermore, while taking current energy usage into account, the World Coal Institute estimates that current coal reserves will last another 130 years, oil reserves for 42 years, and natural gas reserves for 60 years. The need to replace old fossil fuels with sustainable alternatives and new energy scenarios is thus becoming critical. Another major environmental worry is the rising quantities of carbon dioxide (CO_2) in the atmosphere, which is caused by the combustion of fossil fuels and contributes to global warming [24].

Carbon capture allows for the production of low-carbon power from fossil fuels as well as the reduction of CO_2 emissions from industrial operations, such as gas processing, cement production, and steel production, where alternative decarbonization options are restricted. CO_2 capture and usage is gaining popularity across the world [24].

Human-caused CO_2 increases have disastrous repercussions, such as rising average temperatures, melting sea ice, flooding, and sea level rise, harming global life, health, and the economy. The staggering difference between the total amount of carbon emitted worldwide as CO_2 and the quantity of carbon present in five crucial carbon-containing commercial chemicals, not including derivative products such as ethylene oxide [25], underscores the grave consequences of continued carbon emissions. Even with indirect effects, the greatest quantity of CO_2 that may be used remains quite little in comparison to total emissions. For example, if the whole worldwide yearly manufacturing of ethylene, the most extensively made commercial chemical containing carbon atoms, were carried out solely using carbon derived from CO_2, this would result in direct usage of less than 1.5 percent of total global CO_2 emissions [26]. Even with additional commercial chemicals included and indirect mitigation assumptions applied, possible usage might constitute just a tiny fraction of overall emissions. Naturally, this ignores the reality that direct CO_2 conversion into hydrocarbons, particularly aromatics, is unlikely to become a commercial method in the near future.

Nonetheless, CO_2 activation is exceedingly difficult since CO_2 is a completely oxidized, thermodynamically stable, and chemically inactive molecule. Furthermore, hydrocarbon synthesis by CO_2 hydrogenation frequently results in the creation of undesirable short-chain hydrocarbons rather than the desired long-chain hydrocarbons [27]. As a result, most research in this field has been on the sequential hydrogenation of CO_2 to CH_4, oxygenates, CH_3OH, HCOOH, and light olefins (C_2–C_4 olefins). There have been few experiments on creating liquid hydrocarbons with molecular weights of C^{5+}.

There are two methods of converting CO_2 to hydrocarbon gas liquids: an indirect pathway that transforms CO_2 to carbon monoxide (CO) or methanol and then to liquid hydrocarbons, or a direct CO_2 hydrogenation route that combines CO_2 reduction to CO through the use of the converse water-gas shift reaction shift (CWGS) and subsequent CO hydrogenation to long-chain hydrocarbons through the use of the Fischer-Tropsch synthesis (FTS) [28,29]. Secondly, the more direct technique is typically viewed as cheaper and ecologically acceptable since it requires fewer chemical process stages and uses less energy

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

overall. The following chemical reactions are relevant for the production of hydrocarbon fuel (Scheme 1).

Hydrogenation of CO_2:

$$CO_2 + 3H_2 \rightleftharpoons CH_2 + 2H_2O \ (\Delta H^0_{298} = 125 \text{ kJ mol}^{-1};$$

The CWGS reaction: $$CO_2 + H_2 \rightleftharpoons CO + H_2O \ (\Delta H^0_{298} = 41 \text{ kJ mol}^{-1}); \text{ and}$$

The FTS reaction: $$CO + 2H_2 \rightleftharpoons -(CH_2)- + H_2O \ (\Delta H^0_{298} = -166 \text{ kJ mol}^{-1})$$

Scheme 1. Chemical reactions used to produce hydrocarbon fuels.

Mitigation of greenhouse gases is one of the most pressing issues confronting society today. As a result, the best strategy to minimize greenhouse gas emissions is to employ carbon-free sources that do not emit more CO_2 into the environment [30]. However, there is significant promise in CO_2 energy carriers and other materials, with several hurdles to overcome. Reduced CO_2 emissions and conversion to renewable fuels and valuable chemicals have been proposed as possible ways to reduce greenhouse gas emissions [30].

This review discusses the most current breakthroughs and problems in CO_2 use for effective renewable fuel (RF) synthesis. This comprises revolutionary technologies, techniques, and existing impediments to CO_2 to RF conversion, with the goal of establishing advancements in this field and presenting an overview of recent research trends for the prospective development of new concepts for large-scale CO_2 reduction into methanol.

2. Global Warming and Sustainability

Producing energy from CO_2 rather than absorbing and disposing of it is a sustainable energy technique. In reality, several thermochemical processes may transform CO_2 into value-added compounds such as hydrogen, methanol, and ethanol [31]. These fuels may be utilized to power automobiles without requiring major modifications to existing internal combustion engines, paving the way for a more sustainable future. Discovering eco-friendly alternatives and new energy scenarios, primarily the conversion of CO_2 into value-added chemicals using sunlight, is one of the top-most research priorities to overcome today's extreme reducing the use of fossil fuels and mitigate the global warming risks associated with high CO_2 concentrations in the atmosphere [32].

Because of decreased prices, quick commercial adoption, and complete industrial development, the use of second-generation green fuels is one of the most promising approaches to achieving industrial and ecological aims in the short term. A green fuel, unlike fossil fuel, does not emit more CO_2 into the atmosphere since its burning, in the well-to-wheel cycle, creates a CO_2 release equivalent to that required for its manufacture, closing the CO_2 balance, and making it a carbon-neutral fuel [33]. The practical application of hydrogenation catalysts in conjunction with commercially viable research and innovation technology. Indeed, catalytic conversion of atmospheric CO_2 into biofuels and fine chemicals would be one of the most economical and realistic solutions to the problem of greenhouse gas emissions, assuming that capture/sequestration and high-pressure storage technologies become commercially viable [34,35]. Nonetheless, in a very short time, the most prosecutable actions and encouraging prospects look upon the use of CO_2-rich streams originating from industrial exhaust emissions, such as brick and cement work, despite the need for clean-up stages, as well as additional purification and concentration [36]. Haldor-Topsoe is at the vanguard of using CO_2 as a carbon feedstock through various power-to-gas technologies, whereas ENI is redesigning its production lines with a greener vision, by developing new hydrogenation processes, called ENI Ecofining^{TM}, for green-fuels synthesis, advantageously depicting the production of ultra-pure CO_2 as industrial

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

practice [37]. Despite significant advances in fuel science, the commercial and economic viability of hydrogen-to-liquid-fuels such as methanol is still being debated. The discovery of more effective catalyst substances for the efficient hydrogenation of CO_2 looks to be of major importance in this scenario. CuO/ZnO-based catalysts, as is well known, offer lower costs and improved chemical stability when compared to other catalysts such as transition metal carbides (TMCs), bimetallic catalysts, or Au-supported catalysts [38]. Although $CuO/ZnO/Al_2O_3$ is the most extensively investigated catalyst for methanol synthesis, it was shown that the inclusion of ZrO_2, CeO_2, and TiO_2 oxides improved both the activity and selectivity of CuO/ZnO-based catalysts in CO_2 hydrogenation processes [39].

Recently the influence of replacing Al_2O_3 with CeO_2 in the typical $Cu\text{-}ZnO/Al_2O_3$ catalytic discussed composition for syngas conversion, suggesting that the use of cerium oxide led to a remarkable positive effect on the catalyst stability, as a result of the preservation of the ratio of CuO/Cu^+ on the catalyst surface. As well as, on the particle growth, due to the strong electron interactions of the copper/ceria phase ($Cu/Cu_2O/CuO$, Ce^{3+}/Ce^{4+}) during hydrogenation reactions [40]. Metal dispersion and CO_2 adsorption capacity are two key parameters affecting the CO_2 hydrogenation functionality of Cu-based systems. Similarly, in our previous works, we displayed that the use of several oxides (i.e., ZnO, ZrO_2, CeO_2, Al_2O_3, Gd_2O_3, Ce_2O_3, and Y_2O_3) and alkaline metals (i.e., Li, Cs, and K) could remarkably influence both catalyst structure and morphology, balancing the amount of the diverse copper species (i.e., $Cu^\circ/Cu^+/Cu^{2+}$) and leading to a notable improvement of the catalytic performance. On this account, ZrO_2 has been shown to positively the affect morphology and texture of Cu-ZnO based catalysts, also favoring CO_2 adsorption / activation and methanol selectivity, while CeO_2 could act as both an electronic promoter and improver of surface functionality of Cu phase [41]. As reported in our preliminary works, the scientists have proved a greater specific activity of $CuZnO\text{-}CeO_2$ catalyst with respect to that of similar catalytic systems containing ZrO_2 or other promoter oxides, facing several electronic and structural effects. Despite of a generally higher specific activity, we have evidenced that the CuZnO-Ceria catalyst suffers from several practical limitations, such as: a lower surface area, especially compared to that of ZrO_2 and Al_2O_3 promoted catalysts.

3. Green Hydrogen and Biofuel

Hydrogen has several benefits as an energy carrier and will play a key role in future energy production and circular economy [42]. Because hydrogen can be created in a climate-neutral way and emits only water when used, it is regarded as a climate-friendly energy carrier [43]. Hydrogen derived from renewable sources is commonly referred to as "green hydrogen." It contrasts with "grey hydrogen," which is defined as hydrogen derived from fossil, nonrenewable sources [44]. Currently, grey hydrogen generated by steam reforming of fossil natural gas accounts for the majority of worldwide hydrogen production [44]. Grey hydrogen may be converted to "blue hydrogen" by using carbon capture and storage technology, but it remains a non-renewable source [45]. To distinguish between carbon-neutral green and blue hydrogen, we coined the term "carbon-negative hydrogen." Hydrogen has a wide range of uses due to its high gravimetric energy density, as well as its ease of storage and transportation [46]. Fuel cells may produce both electric power and heat from hydrogen. In the steel industry, hydrogen may also be utilized as a reducing agent [46]. It is regarded as an unavoidable basic building element in difficult-to-electrify zones [46]. Green hydrogen may be created using renewable power or renewable biomass, either through thermochemical processes or using microorganisms and biotechnological technologies. Biohydrogen, or hydrogen generated from biomass, can lead to more effective use of biogenic source materials by using residual and waste materials. Biohydrogen production technologies are classified as thermochemical or biotechnological. Biohydrogen may be generated on an industrial scale utilizing thermochemical methods from biomass (wood, straw, grass clippings, etc.) as well as other bioenergy sources (biogas, bioethanol, etc.) [43]. Gasification and pyrolysis are two types of thermochemical reactions. The synthesis gas produced by gasification or pyrolysis contains varying proportions of

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

H_2, CO_2, carbon monoxide (CO), methane (CH_4), and other components such as nitrogen, water vapor, light hydrocarbons, hydrochloric acid, alkali chlorides, Sulphur compounds, biochar, or tar [47]. The following chemical processes occur as a result of subsequent steam reforming and/or water gas shift reactions, culminating in the creation of CO_2 and hydrogen [48]. Minimal carbon-hydrogen (MCH) should be used initially in areas that are difficult to electrify directly [49]. We believe that generated bio-hydrogen is employed in difficult-to-electrify industrial sectors such as cement, steel, refining, ammonia, and glass. Refineries and ammonia plants are now the largest customers of hydrogen generated by steam methane reforming, a process that releases at least 10 kg CO_2 for every kilogram H_2 produced. Because many industries utilize carbon-intensive hydrogen, switching to MCH would be a near-term opportunity to increase hydrogen demand while lowering greenhouse gas emissions. Companies that are difficult to electrify may reduce their emissions and capture carbon dioxide by switching to alternative fuels and implementing carbon capture and storage technologies. This can help to enable their operations to contribute to the elimination of carbon dioxide from the atmosphere.

Country-specific forecasts of European nations' ultimate energy consumption in 2050 are unavailable and difficult to determine. As a result, scientists evaluate country-specific final energy consumption in 2019 and anticipate that 5–30% of final energy consumption will be fulfilled with low-carbon hydrogen to minimize hard-to-electrify emissions. These scenarios enable us to set upper and lower bounds on the amount of hydrogen likely required by each European country to achieve net-zero emissions by 2050 [50].

4. Carbon Dioxide Sequestration by Microalgae

Carbon dioxide (CO_2) sequestration and stabilization technologies are methods designed to reduce the amount of carbon dioxide emissions in the atmosphere, in order to mitigate the effects of climate change. CO_2 sequestration refers to the process of capturing and storing CO_2 from industrial processes or power generation, while CO_2 stabilization refers to methods that aim to reduce the amount of CO_2 emitted into the atmosphere. There are several types of CO_2 sequestration technologies. Carbon capture and storage (CCS) is a proven technology that has been used for several decades in various industries. It has the potential to capture a significant portion of CO_2 emissions from industrial processes and power generation, and to store them safely underground [51]. However, CCS is currently expensive and requires significant infrastructure, and there are concerns about the long-term integrity of storage sites and potential leaks [51]. Direct air capture (DAC) is an emerging technology that has the potential to capture CO_2 directly from ambient air, regardless of the source of emissions [52]. It could be useful for decarbonizing industries that are difficult to electrify, such as aviation or shipping. However, DAC is currently expensive and energy-intensive, and there are concerns about the scalability of the technology [52]. Carbon capture and utilization (CCU) can help to reduce emissions while also creating new economic opportunities [53]. It has the potential to be cost-effective, especially if the captured CO_2 can be used to produce high-value products. However, the scale of CCU is currently limited, and it may not be feasible for all industries or applications.

Enhanced oil recovery can help to reduce emissions while also increasing oil recovery. It has been used for several decades and is a well-established method. However, it is limited to areas with suitable oil reservoirs, and the potential for CO_2 leakage or other environmental risks must be carefully monitored. Mineral carbonation is a promising method that has the potential to store CO_2 in a stable and long-lasting form [54]. It could be particularly useful for capturing CO_2 from industrial processes that produce high-purity CO_2 streams. However, the process is currently expensive and requires significant energy inputs.

It is critical to improve existing technology and find appropriate replacements. In comparison to physical and chemical approaches, biological CO_2 fixation (CDF) appears to be a more cost-effective and environmentally beneficial solution. Photosynthetic organisms ingest CO_2 during the dark period of photosynthesis and serve an important role in

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

maintaining the equilibrium of CO_2 levels in the atmosphere [55]. Phytoplankton showed better CDF capacity and biomass output when compared to other green organisms [56]. Marine phytoplankton provides for half of the total global primary productivity, fixing 50 gigatonnes of CO_2 every year [57]. In this context, experiments on carbon capture by microalgae have piqued the interest of scientists all around the world. Microalgae can absorb CO_2 10–50 times more efficiently than vascular plants while not competing with or supplying food for humans/animals [57]. The carbon concentration process is a specific mechanism used by microalgae to ingest carbon dioxide. The pyrenoid, a specific organelle, raises the level of CO_2 near the thylakoid membranes in this process [58]. The rising carbon dioxide content near the thylakoid membrane increases the effectiveness of ribulose-1,5-bisphosphate carboxylase/oxygenase, a key photosynthetic enzyme for carbon uptake or sequestration.

In order to accomplish sustainability goals, not only economic elements but also social (protection or hazard-free), environmental (pollution prevention and regulatory authority), energy, material, and economic performance aspects of processes and products must be reviewed, optimized, and regulated [59]. Furthermore, these process control systems should protect against unforeseen instabilities that occur when the process deteriorates over time and/or because of changes in feed composition flow rate, temperature, and pressure. Furthermore, a hierarchical design technique was presented to synthesize economically efficient separation procedures while considering environmental concerns as limitations [60]. Recently, a modular strategy for designing sustainable chemical processes was established by combining quantitative economic and environmental variables with qualitative social indicators [61]. Multi-objective optimization systems have a greater chance of achieving the best trade-off between competing economic and environmental goals. For instance, a universal optimization technique for sustainability was created, in which a large-scale algae processing network was concurrently optimized in terms of lowering the unit cost- and global warming ramifications indicators [62]. A multi-objective genetic algorithm was employed to address an integer non-linear programming problem related to environmental concerns, despite it having a single objective. The algorithm was able to optimize for multiple factors simultaneously, allowing for a more comprehensive and effective solution. Sustainable process control research for chemical processes, on the other hand, is not as well recognized as sustainability design optimization. There has been little published research on process operations that use sustainability-oriented control techniques [63]. To address the sustainability of a batch reactor, a strategy incorporating stochastic dynamic optimization with optimum control was presented [64]. Another use of deterministic optimum control techniques to increase energy efficiency in industrial processes has been documented [65]. Only utility-related environmental consequences were examined in these two investigations. Given the contradicting nature of sustainable indicators, this constraint might be linked to a lack of effective solutions for integrating process sustainability features into the advanced controller architecture (e.g., economics vs. environment) [65]. According to the principles of green chemistry and engineering [66], chemical production processes that reduce or limit greenhouse gas emissions of hazardous substances should be developed by minimizing waste, performing real-time analysis regulating contamination and dangerous incident prevention, maximizing mass, energy, space, and time efficiency, and so on [66]. Furthermore, when improved sustainability is established, it must be maintained in the face of any beyond-the-gate (front-edge alterations) and/or process stage disturbances. Catalytic, electrochemical, mineralization, biological (using microorganisms and enzymes), photocatalytic, and photosynthetic processes are among the various technical pathways available for converting CO_2 into commercial goods [67]. Electrolyzers are used in electrochemical processes to convert CO_2 to CO. H_2, which is often produced by water electrolysis, is a common co-reactant in the conversion of CO_2 to CH_4, CH_3OH, and other compounds. Electrolysis techniques are energy-intensive and expensive [68]. Near-zero emission energy sources must be employed for the systems to be carbon-neutral. CO_2 electrolysis is a more new study topic than H_2O electrolysis, which is well known, and thus

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

more effort is needed to develop affordable, robust catalytic materials with high efficiency, selectivity, and yield [26]. Energy efficiency, Faradaic efficiency, conversion rate, long-term catalyst(s) stability and durability, and process economics are five critical system-level aspects to consider when commercializing these technologies. The primary distinction between photocatalytic and electrochemical CO_2 reduction is the source of electrons, which are acquired in the former by exposing semiconductors to light and in the latter by providing a current [68]. The direct utilization of photons, as opposed to the first conversion into electricity, is a significant benefit of the photocatalytic process. However, such processes are complicated, including several mechanisms that are not fully understood, such as electron and proton transport and chemical bond formation/breaking [68]. Solar-energy-driven CO_2 conversion has sparked tremendous interest across the world, with research focusing mostly on the creation of innovative nanomaterials photocatalytic materials and laboratory-scale examination of the reaction process. Efficiency is critical for affordability and scalability in any system that uses solar power for CO_2 conversion [69]. Currently, the attainable CO_2 conversion rates of photocatalytic/photothermic catalytic systems in development are frequently low and impractical for commercial-scale operations. Because the electrochemical or photocatalytic reduction of CO_2 to create high-specificity chemicals or fuels is difficult, it may be easier to employ some well-established catalytic techniques to react CO_2 and H_2 to form carbon-based products [70]. The catalyst—the substance that transforms CO_2 that must have high efficiency, selectivity, quick reaction rates, and stability—is at the core of various CO_2 conversion methods. CO_2 conversion catalysts are actively researched and developed across the world [71]. A number of catalysts have been developed and tested, and they have proven to be capable of converting CO_2 into a variety of compounds with high efficiency, selectivity, and yields. Several papers available discuss current advances in catalyst reactor design [72]. More research is needed to make these catalysts more efficient, selective, and stable over time. More effort is needed to create technologically and economically feasible procedures for the commercial conversion of CO_2 into fuels and chemicals based on these catalysts. Furthermore, one crucial technology for the competitiveness of CO_2-derived chemicals and fuels on the market is the low-cost synthesis of carbon-free H2 [73]. These reactions need pure CO_2; hence, CO_2 released from sources such as fossil fuels are insufficient. In general, these processes demand pure CO_2, hence CO_2 released from sources such as fossil-fuel power plants, steel, and cement production must be cleaned, raising the prices even higher. Biotechnology relies on the capacity of living organisms such as microbes, algae, or plant cells to metabolize one material into another.

Numerous studies over the last decade have demonstrated that CO_2 mitigation using algae is a sustainable process with the simultaneous synthesis of high-calorific products such as biodiesel, pigments, fatty acids, and so on [74,75]. The broad dispersion, high biomass output, capacity to respond under harsh conditions, rapid carbon absorption and consumption, and ability to develop value-added products all contribute to algae's potential usage (Figure 1 and Table 1). The carbonic anhydrase enzyme is used by both macro and microalgae to digest inorganic carbon via a photoautotrophic process [76]. The $NADH_2$ produced by the electron transport chain joins with the Ribulose-1,5-bisphosphate carboxylase/oxygenase (supplied by the carbonic anhydrase enzyme) and aids in carbohydrate creation from CO_2 as well as providing limited power in the Calvin cycle for glucose synthesis [77]. There were also numerous more strains of microalgae that grew rapidly under harsh environments such as high pH and temperature [78]. Lipids, which may be utilized as a source for biofuel production (e.g., biodiesel), are the most industrially useful algal product [79]. As a result, a diverse set of strains for high lipid synthesis and boosting growth parameters like as light, temperature, and pH are critical to increasing productivity [80]. Unoptimized pH during algae development can influence carbon species distribution and carbon availability. Furthermore, at high pH levels, it can have a direct impact on the metabolic activity of algae.

Figure 1. Green conversion of CO_2 to biofuel.

Green algae species such as *Chlorella vulgaris* and *Nannochloropsis gaditana* were studied for CDF in tubular bioreactors under optimal conditions of temperature (25 C), CO_2 concentration (4 and 8 volume percent), and artificial light [81]. The greater CDF in both species was sustained by an 8 volume percent CO_2 concentration. When compared to other species, *Nannochloropsis gaditana (N. gaditana*) had a greater CO_2 biofixation rate (1.7 g/L/day) and cell concentration. Overall the biological control applications offer a promising solution for reducing carbon dioxide emissions and bioconverting them into renewable fuels (Table 1). Researchers have been exploring the use of enzymes found in nature to catalyze the conversion of carbon dioxide into sustainable fuel. Enzymes are highly efficient and selective catalysts, and by mimicking their structure and function, researchers hope to develop new catalysts with improved performance and sustainability.

Table 1. Some biological control applications for carbon dioxide stabilization and bioconversion into renewable fuels.

Target	Method	Enzymes	Species	Product	Pathway	References
Changing heterotrophic yeast into autotrophs capable of utilizing carbon dioxide as their sole carbon source	Isotopic tracing, metabolic rewiring, gene modification, responsive laboratory evolution	cbbM, groEL, groES, PGK1, TDH3, TPI1, TKL1,	*Pichia pastoris*	Biomass	Calvin-Benson-Bassham (CBB)	[82]

Two microalgae species (*Chlorella sp.* and *Tetraselmis suecica*) were studied for growth kinetics, pH, and biofixation at various CO_2 concentrations (0, 5, 15, and 30%) [91]. Both species demonstrated varying degrees of tolerance to CO_2 concentrations. The optimal pH varied from 7.5 to 9. Both species' biomass were fermented by Clostridium saccharoper-butylacenaticum N1 4, which generated value-added biochemicals such as organic acid (acetic acid and butyric acid) and solvent (acetone, butanol, and ethanol). *Chlorella vulgaris* was tested using various colored light filters and unfiltered light [92]. The white-colored filter had the highest biomass content (2.26 g/L). The important factors of the process, such as carbon sources and concentrations, pH conditions, buffering agent, H_2 gas (as electron donor), and CO_2 availability, were investigated in the manufacturing of succinic acid using a strain strongly tied to *Citrobacter amalonaticus* [93]. The study's findings revealed that utilizing sucrose as a substrate including H_2 and CO_2 resulted in the highest synthesis of succinic acid (12.07 g/L), as well as the removal of by-products (formic, lactic, and acetic acids). A 900 L tangential spiral-flow column photo-bioreactor was assessed in a recent study [94] to optimize the light distribution and light/dark cycle for better CO_2 fixation utilizing *Arthrospira sp.* The higher cell concentration aided total photosynthesis and improved CO_2 fixation by 59%. The cells obtained maximal values of chlorophyll a content (8.769 mg/L), helix pith (78.26 m), and CO_2 fixation rate of 0.358 g/L/day with a

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

CO_2 aeration rate of 0.210 L/min, the CO_2 volume concentration of 15%, and circulating pump power of 30 W. For kinetic modeling of *Chlorella vulgaris* growth and CO_2 fixation, a central composite design-based statistical technique was used [95]. Temperature, CO_2 concentration, nutrients (N, C, and P), gas flow rate, light intensity, and initial inoculum concentration were all taken into account. Under optimized conditions, the highest optimum growth and CO_2 fixation with an energy ratio of 19.5 were obtained: temperature, 25 °C; CO_2 concentration, 20%; gas flow rate, 0.5 vvm; total nitrogen, 19 mg-N/L; total phosphorous, 7 mg-P/L; initial concentration of inoculum, 0.52 mg/L; and light intensity, 150 μE/m^2s. Approximately one-third of the sugar substrate is lost as CO_2 during microbial fermentation (pyruvate decarboxylation to acetyl-CoA) [96]. *Clostridium acetobutylicum* (which eats sugars to create a range of compounds in addition to releasing CO_2 and H_2) and *Clostridium ljungdahlii* (which fixes CO_2 via the Wood-Ljungdahl pathway) were employed to repair the released CO_2 [97]. This co-culture was successful in recovering carbon and producing non-native metabolites isopropanol and 2,3-butanediol. Based on the H_2 substrate, the wood-Ljungdahl route is efficient for creating acetate and ethanol. This method has been used to successfully produce alkanes [98], acetone and acetate, and lipids for biodiesel synthesis from CO_2.

Microalgae have a high biomass production and are resistant to harsh environmental conditions. As a result, microalgae are being explored as a possible feedstock for Sequestration and bioenergy generation [78,99]

The growing methodology, microalgal strain, flue gas composition, CO_2 tolerance capability, and other factors all contribute to the issues involved with algae-based carbon sequestration [78]. In the biomass cultivation stage, operating costs and energy consumption are increased. Several studies have shown that an open lagoon is more expensive for algae production, but it is not a suitable choice for preserving cultural integrity. The dynamics of heat transmission, irradiance, and nutrient status have been explored, and it has been discovered that thermal modeling is critical for the open raceway, as outlined in [100]. Life cycle assessment (LCA) is an effective method for measuring input-output inventories, power consumption, cost, and the entire life cycle. The LCA of microalgae carbon sequestration begins with microalgae growing and progresses to product creation. A detailed LCA on microalgae generation and flue gas sequestration in raceways ponds revealed that the semicontinuous culture system had a 3.5-fold greater rate of growth for biomass productivity than batch cultivation. The study also found that flue-gas-fed outdoor raceway ponds (RPs) might reduce GHG emissions by 45–50% compared to the baseline [100]. According to another LCA assessment, the cost of producing biomass is 4.87 USD per kilogram, and the energy usage is 0.96 kWh/kg of *Chlorella* biomass. Under natural daylight circumstances, 4000 m^3 algae culture ponds might sequester up to 2.2 k tonnes of CO_2 per year, according to one research [101]. Another research found that 50 MW power stations may emit 414,000 t/year CO_2, whereas a 1000-ha open RPs could absorb 250,000 t/year CO_2. According to this study, algae might cut CO_2 emissions by 50%. A primary obstacles to indirect CO_2 extraction from industrialized flue gas utilizing microalgae is that flue gas includes 142 chemical components that are potentially harmful to microalgae [4]. The low amounts of NOx and SOx in flue gas can provide nutrients to microalgae, while greater concentrations can be hazardous. CO_2 solubilization (CDs) in culture media is primarily determined by pH, temperature, and salt content. Numerous growth media have high salinity, which raises osmotic pressure and, as a result, inhibits CDs in the medium. Feed-batch cultures, for example, can be used to progressively deliver the salts required for microalgal development [102]. Various studies have demonstrated the specialized suitability of algal CO_2 sequestration; however, the crucial problems are the key and all circumstances of improvements that will enhance the financial functionality of algal CDS and contribute to making this a rational advanced method to deal with GHG remediation. Microalgae carbon sequestration is a long-term strategy for reducing global CO_2 emissions [103]. Microalgae is a more appropriate alternative for carbon emission reduction due to recent advancements in culture conditions, harvesting, CDS capability,

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

and LCA studies [103]. The majority of research has been on determining how to select and cultivate several potential microalgae species for effective CDS. There has been little focus on the establishment of large and commercial-scale carbon sequestration utilizing microalgae. Most of the study has focused on how to identify and develop several possible microalgae species for successful CDS. There has been a minimal emphasis on the development of large-scale and commercial-scale carbon sequestration using microalgae. Though research in algal carbon sequestration mostly concerns strain mutation, improved growth techniques, and harvesting, there is a vacuum in the area involving variables influencing carbon sequestration (e.g., change in light intensity over the day (month, and year), and so on. Likewise, pyrenoid is the most significant sub-organ of microalgae that plays a vital function (as stated above in a separate area) in the carbon concentration process, but research in this field is still in its early stages. Furthermore, research on high-CO_2-tolerant microalgae is required to improve carbon sequestration. More research is needed to determine how to minimize the loss of residual undamaged carbon [104].

However, there are also some challenges to overcome in using biotechnology for CO_2 sequestration. For example, the productivity and stability of the organisms used must be optimized to ensure that they can capture and convert CO_2 efficiently and consistently. Additionally, the processing methods for the products produced must be cost-effective and scalable to enable commercial viability [105]. The carbon neutrality of green fuels is achieved through the use of renewable resources such as biomass, wind, or solar energy to produce the fuel. During the production process, renewable resources absorb carbon from the atmosphere through photosynthesis or other natural processes [106]. This carbon is converted into fuel through various conversion processes, such as fermentation or pyrolysis. When green fuel is burned, it releases carbon emissions into the atmosphere, but these emissions are balanced by the carbon absorbed during the production process. This creates a closed carbon cycle, where the carbon emitted during fuel use is reabsorbed during the production process, resulting in no net increase in carbon emissions. It is important to note that the carbon neutrality of green fuels depends on various factors, including the source of raw materials, the efficiency of the conversion process, and transportation emissions. A comprehensive lifecycle analysis is necessary to accurately assess the carbon footprint of green fuel and determine whether it is carbon-neutral [107].

Overall, biotechnology, particularly the use of microbes, algae, or plant cells to metabolize one material into another, is a promising approach for CO_2 sequestration and stabilization. Further research and development will be needed to optimize the efficiency, selectivity, and cost-effectiveness of these approaches, but they hold significant potential for addressing the challenges of climate change and reducing greenhouse gas emissions.

5. Future Perspective

The green conversion of CO_2 into sustainable fuels is a rapidly evolving field, with many promising developments on the horizon [69]. The integration of multiple technologies and approaches to optimize the CO_2 conversion process. For example, researchers are exploring the use of renewable energy sources, such as solar and wind power, to power the CO_2 conversion process. This approach would enable the production of sustainable fuels without relying on fossil fuels, further reducing greenhouse gas emissions [108].

The development of scalable and cost-effective CO_2 captures technologies and the widespread adoption of sustainable fuel synthesis will require the capture of large amounts of CO_2 from industrial processes and the atmosphere. Current CO_2 capture technologies are often expensive and energy-intensive, limiting their feasibility on a large scale. However, researchers are developing new capture technologies based on materials such as metal-organic frameworks and zeolites, which have the potential to significantly reduce the cost and energy requirements of CO_2 capture [109].

The integration of Artificial intelligence and machine learning algorithms is also expected to play a significant role in the future of CO_2 conversion [110]. As these algorithms become more advanced, they will be able to optimize the CO_2 conversion process with

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

greater accuracy and speed, leading to further improvements in efficiency and selectivity. These technologies are still in their early stages of development and will require significant investment in research and development to optimize their efficiency and reduce costs. Many of these technologies rely on renewable energy sources such as solar and wind power. Therefore, the increased deployment and use of renewable energy sources will be critical for the success of these technologies. These technologies must be cost-effective and scalable in order to be implemented on a large scale. The development of cost-effective systems will require a focus on reducing the costs of materials and improving the efficiency of conversion processes.

Governments and policy makers can play a critical role in supporting the deployment and adoption of these technologies through supportive policies such as incentives, subsidies, and regulations [111]. Widespread public awareness and acceptance of these technologies will be important in driving demand and accelerating their adoption.

The future of these technologies will require a combination of technological innovation, supportive policies, and public engagement in order to achieve their full potential in addressing climate change and achieving a sustainable future.

The widespread adoption of these technologies will require the development of new infrastructure to support their deployment. This includes infrastructure for carbon capture, storage, and transport, as well as new facilities for the production and distribution of sustainable fuels.

Collaboration and knowledge sharing among researchers, industry, and government entities will be crucial for the successful implementation of these technologies. This will help to foster innovation, reduce costs, and accelerate the development of new technologies and processes.

The implementation of these technologies must also take into account environmental and social considerations. For example, the development of infrastructure for carbon capture and storage must be done in a way that minimizes potential environmental impacts, and the production of sustainable fuels must be done in a way that does not compete with food production or result in other negative social impacts [112,113] Public-private partnerships can play a critical role in the development and deployment of these technologies. Governments can provide funding and supportive policies, while the industry can provide expertise, technology, and investment.

International cooperation will be necessary to address the global nature of climate change and to ensure that these technologies are deployed in a way that is equitable and sustainable for all nations.

In summary, the successful implementation of the green conversion of carbon dioxide and sustainable fuel synthesis technologies will require a combination of technological innovation [114], supportive policies, public engagement, collaboration, infrastructure development, environmental and social considerations, public-private partnerships, and international cooperation.

6. Conclusions

The green conversion of carbon dioxide and sustainable fuel synthesis offers a promising path toward a more sustainable and low-carbon future. By continuing to invest in research, development, and policy support, we can unlock the full potential of these technologies and accelerate the transition to a more sustainable energy system.

The production of green hydrogen, using renewable electricity sources such as wind and solar, offers a promising alternative to conventional hydrogen production methods that rely on fossil fuels. Algae-based biofuels also show potential as a sustainable alternative to conventional transportation fuels, due to their ability to sequester carbon dioxide during growth.

Furthermore, the use of carbon capture and utilization techniques, such as carbon dioxide conversion to chemicals and fuels, can help close the carbon cycle and reduce carbon emissions. The development of sustainable feedstocks and production processes,

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

including bioreactors and other advanced technologies, can also enhance the sustainability and carbon neutrality of fuel production.

It is crucial that policymakers, researchers, and industry stakeholders work together to support the development and implementation of these sustainable fuel production methods. This includes providing policy incentives and funding for research and development, as well as promoting the adoption of sustainable fuel production technologies.

Carbon capture by microalgae was demonstrated. In addition, certain large-scale commercial research appears promising in terms of cutting significant greenhouse gas emissions and preventing global warming. Moreover, when compared to terrestrial plants, microalgae have better carbon dioxide tolerance, carbon absorption efficiency, photosynthetic efficiency, and growth rate. Unlike traditional carbon capture systems, which are largely relevant to power plants, this strategy is appropriate for carbon emissions from the transportation system while also serving as a feedstock for biofuel production for the sector, resulting in reduced emissions.

Overall, the use of green hydrogen, algae-based biofuels, carbon capture and utilization, and sustainable production processes offer promising solutions for reducing carbon emissions and addressing the challenges of climate change. With continued investment in these areas, we can accelerate the transition to a more sustainable and low-carbon energy system.

Published: April 2017

Abstract

To achieve the targeted portion of renewable energy and to attract more investment in renewable electricity Indonesia's government has issued several feed-in-tariff regulation, which is policy instrument successfully applied in many countries. This study is an exploratory research to evaluate how the policy works in Indonesia, especially in the field. The study shows that while the policy triggers investment interests, many obstacles are encountered due to imperfections in the feed-in-tariff policy package, and other non-cost factors. Several unanticipated side effects were also identified as consequences of the upturn in investment interest, indicating that transition to cleaner energy is much more challenging for developing countries such as Indonesia.

Subject: Economic Development and Growth

8.1 Introduction

Indonesia is an archipelago rich in renewable energy resources including geothermal, hydro, biomass, solar, and wind energy. Due to its location in the 'Ring of Fire', geothermal energy is its main potential source of renewable energy, amounting to 29 GW—40 per cent of the world's total. Of the total potential, up till now only 1,340 MW (less than 5 per cent) has been installed for electricity generation, with another 1,500 MW at various stages of development (DGNREEC 2015). Hydropower is another major source of potential in Indonesia and is estimated to be around 75,000 MW. At present, some 6,000 MW has been installed as large Hydro Electric Power, mostly in Java. Included in this category is small hydro (up to 10 MW). 217.16 MW of small hydropower plant has been installed in 2015, a large portion of which is used not for profit but for electrifying remote areas (DGNREEC 2015).

For a country on the equator, solar energy is considered the most under-utilized source of energy in Indonesia. Only around 71 MW is installed but mostly belongs to the state-owned electricity company (SEC or Indonesia's PLN) for electrifying remote islands in the eastern parts of Indonesia. At present, the imported amount of solar photovoltaics (PV) is still considerably high, so the Government of Indonesia (GOI) has attempted to boost the local production of PV systems and encourage investors to build PV manufacturers. As an agricultural country, biomass is the other major potential source of Indonesia's

Downloaded from https://academic.oup.com/book/16547/chapter/172504735 by guest on 24 March 2023

renewable energy. This is thought to have a potential 32,000 MW, of which 1,740 MW is planned to be installed in the near future (DGNREEC 2015). Biomass sources include palm oil, cassava, sugar cane, and so on, which can be the source of bioethanol and biofuel production.

p. 145 Despite this abundant potential, the development of renewable energy in Indonesia still faces a hard battle, mostly because of the long legacy of the government's energy subsidies for fossil fuels. According to the Ministry of Energy and Mineral Resources (MEMR), Indonesia's energy demand has been increasing faster than its economic development growth, which amounted to 7 per cent in 2014 (DGNREEC 2014). This demand is currently met largely by fossil fuels, which in turn bleeds the country's finances as Indonesia has become a net importer of both crude oil and refined products since 2004.

As a response to the increasing demand for energy and for cleaner energy due to climate issues, in January 2014 The National Energy Policy was adopted by the House of Representatives in the form of Government Regulation No 79/2014 (Government of Indonesia 2014), in which the GOI projected that renewable sources would supply at least 23 per cent of Indonesia's energy needs in 2025. The GOI is also committed to reducing greenhouse gas emissions by 26 per cent by 2020 to combat global climate change (MEMR 2015).

Many efforts have been undertaken to increase the deployment of renewable energy (RE), especially to support the increasing electricity demand. These include: obligating the SEC to buy generated electricity from small-scale producers, prioritizing the use of RE, tax incentives, tax holidays for exported equipment, and simplifying the procedure for licences. Lastly, since around 2010 the GOI has implemented its feed-in-tariff (FIT) policy in order to encourage the private sector to develop renewable electricity. The FIT policy ensures that developers get a relatively fair price for electricity generation from renewable energy resources, which are now being used widely in many countries.

This study undertakes exploratory research that aims to evaluate whether the implementation of the FIT policy is effective for the purpose of increasing deployment of renewable energy in Indonesia. A number of official documents and supporting policies set out the plans for renewable energy development in Indonesia. However, no critical study has been carried out into the real outcome of policy implementation in the field. Data analysis is expected to show whether the FIT policy is sufficient, and if not, what are the reasons for this and what can be done to improve it.

This chapter is organized as follows. After the introduction, which describes Indonesia's renewable energy situation and outlines the purpose of the study, Section 8.2 briefly reviews the FIT policy, its principles, case studies, and barriers to implementation. Section 8.3 outlines the methodology used for data collection and the locations covered by the site survey for the purpose of data verification. Section 8.4 provides the data findings and undertakes data analysis to identify factors that hinder the deployment of renewable energy. Section 8.5 offers conclusions and recommendations for better implementation of FIT policy in the future.

p. 146 8.2 A Brief Review of the Feed-in-Tariff Policy

8.2.1 What is FIT Policy?

Historically, to spur the growth of renewable electricity, European countries set a price for electricity that is attractive to investors. This policy, which was subsequently called feed-in-tariff (FIT) policy, has three components: a fixed price which is sufficient for a return on investment, a guaranteed grid connection, and a long-term contract to ensure the stability of the investment (Mendonça 2007). By using this policy, investors do not have to deal with the cumbersome process of various incentives and tax exemptions, as applied in America (Farrel 2009: 6). This price is reviewed annually and it can be lowered if it attracts too many investors or creates windfall profit, and vice versa. Later on, this fixed price policy is accompanied by a mandate for utility companies to connect renewable electricity to the grid. In Europe, the cost of connection to the higher voltage is borne by the utility company, and the contract for selling electricity is short and uniform (Farrel 2009: 6).

According to IRENA (2012), there are four categories of deployment policies, namely: fiscal incentives, public finance, regulations, and access policies (Mitchell et al. 2011). The FIT policy falls into the price-driven public finance policy category (IRENA 2012). Deployment, which is defined by IRENA (2012) as the stage of commercial roll-out, is a stage preceding full competition and maturity in the development of a

Downloaded from https://academic.oup.com/book/16547/chapter/172504735 by guest on 24 March 2023

new technology. In the commercial roll-out stage or deployment, economic support is needed to correct market failure and/or inadequate policy requirements. In the renewable energy market, failure comes from the discrepancy between the average production costs of electricity from fossil fuels or conventional energy and the production costs using renewables. Without consideration of the cost of research and development, externalities related to climate change, and other barriers to mass production, there is no way that renewable energy technology can compete with the energy price produced by conventional technology.

Another benefit of FIT policy implementation includes support for local ownership of renewable plants because of its simplicity, and thus it creates more jobs and increases the economic impact for the community. If we look at the experience of European countries, about half of wind turbines in Germany and about 80 per cent in Denmark are owned by local residents (Farrel 2009).

8.2.1.1 Examples of FIT Implementation

The most notable success story of FIT policy is Germany's and Denmark's experiences in FIT
p. 147 implementation. Germany started to apply FIT policy in ↳ 1990, when the law required electricity utilities to connect renewable electricity to the grid and to buy the electricity at a price ranging from 65 per cent to 90 per cent of the average tariff for consumers (Mez 2012: 24). The implementation of FIT since then has spurred the expansion of wind turbine power plants in particular, from 20 MW in 1989 to more than 1,100 MW in 1995 (Lauber and Mez 2006 in Mez 2012: 24). In addition, Germany has also implemented a wind power programme and provides several kinds of subsidies and financial incentives for renewable energy investors. This policy, along with the implementation of the Renewable Energy Sources Act (RESA) in 2000, which was passed in order to achieve the targeted 25 per cent reduction of carbon-dioxide emissions, has resulted in an almost tenfold expansion in renewables from 1.3 per cent in 1990 to nearly 11 per cent in 2011 (Mez 2012: 26).

In 1988, Denmark applied a price policy for renewable electricity that paved a way for FIT policy, in which utility companies are required to set a fair price, purchase, and connect to the renewable electricity produced. This policy was successful in triggering the establishment of wind turbines, reaching 300 MW of capacity. The FIT policy was formally applied in Denmark in 1993, when the purchase price of renewable electricity was set at 85 per cent of the average production and distribution cost and connection to the grid and purchase of power was guaranteed. This policy, along with an exemption for cooperatives from paying, has resulted in 28 per cent of Danish energy coming from renewables with wind turbines producing almost 3,000 MW of electricity. However, in 2004 the Danish ended the FIT policy and nowadays investors in renewable energy have to follow the renewable energy portfolio standard with tradable credits, such as applied in the USA (Farrel 2009).

8.2.1.2 Barriers to FIT Implementation

Klein et al. (2010) warned that FIT policy should be kept transparent and not too complex, and their study evaluated the structure of electricity tariffs in several countries that could act as barriers to FIT implementation. In the USA, Farrel (2009) complains that the contract for electricity purchase can exceed 100 pages, while in Germany, for instance it is kept short to 4–5 pages. Another potential barrier is the condition of the electricity market, such as liberalization of electricity in New Zealand (White, Lloyd, and Wakes 2013).

However, another study in the European Union has suggested that the poor effectiveness of FIT policy is mainly caused by failure to tend to non-economic barriers, such as uncertain and lengthy administrative processes, and difficulties in gaining access to the grid (IRENA 2012: 13). Research by ECORYS (2008) into European Union member states showed that there are some non-cost barriers that negatively impact the
p. 148 deployment of renewables to a different degree. One of the barriers most impacted is the administrative ↳ hurdles which include many issues, such as lack of coordination between institutions, length of time for obtaining authorization, the incoherence of procedures and regulations, big overhead costs, insufficient spatial planning, and social opposition. Other significant barriers are difficulty in getting grid connection and access, and limited information and awareness related to renewable energy among civil servants and the community in general (ECORYS 2008).

8.2.2 FIT Policy in Indonesia

In Indonesia, a policy, which is similar to FIT, was issued in 2002 for small-scale hydropower plants. The MEMR issued a requirement for the SEC to buy electricity at 60 per cent of regional electricity production costs for low-voltage, and 80 per cent for middle-voltage connection. However, there have been some obstacles encountered in its implementation, one being the difficulty of determining the regional standard of production cost, and another being because energy production (especially of petroleum) was still heavily subsidized by the GOI, so that the utility company did not need to prioritize the use of renewable energy. The policy was improved in 2006 to include higher-scale hydropower plants (up to 10 MW), and then underwent some revisions in 2009 to include a more attractive tariff. Hasan and Wahjosudibjo (2014) argue that the obstacles to FIT implementation are mainly because there is no guarantee of long-term contracts and nor that the utility company will accept the contract.

p. 149 A more formal kind of FIT policy was issued in 2011 and 2012, when the MEMR required the PLN to buy electricity from geothermal power plants at a fixed tariff of US$0.97/kWh. Subsequently, the FIT for other renewable energy sources, such as solar and biomass, was issued in 2013 and 2014. In general, FIT regulation is targeted at reducing the time required for negotiating a price with the SEC (which, at times, can be several years), and making investment more attractive and long-term planning possible, thereby making RE investment viable. Table 8.1 shows the different FIT regulations for various RE sources, their original version, and the revisions.

Table 8.1. Regulation of feed-in tariff in Indonesia for various RE sources

No	RENEWABLE ENERGY SOURCE	FEED-IN TARIFF REGULATION				NOTE
		Original Version	Electricity Price (US$/kWh)	Revised Version	Electricity Price (US$/kWh)	
1	Micro/Mini Hydro	MEMR Regulation No. 12 year 2014	<10 MW = 8 cent	MEMR Regulation No. 22 year 2014	<10 MW = 8 cent	7.2 cent if using public infrast, i.e., irrigation
			>250 kWh = 9.4 cent		>250 kWh = 9.4 cent	8.4 cent if using public infrast, i.e., irrigation
				MEMR Regulation No. 19 year 2015	<10 MW = 12 cent	10.8 cent if using public infrast, i.e., irrigation
					>250 kWh = 14.4 cent	13 cent if using public infrast, i.e., irrigation
2	Geothermal	MEMR Regulation No. 02 year 2011	on high volt. only 9.7 cent	MEMR Regulation No. 22 year 2012	on high volt. 10–17 cent	depend on location
					on med. Volt. 11.5–18.5 cents	
3	Biomass	MEMR Regulation No. 04 year 2012	9.75 cent	MEMR Regulation No. 27 year 2014	8.5 cent	med volt. Interconn.
			13.5 cent		11.1 cent	low volt. Interconn.
	Biogass		9.75 cent		8.5 cent	med volt. Interconn.
			13.5 cent		10.4 cent	low volt. Interconn.

PERPUSTAKAAN NASIONAL REPUBLIK INDONESIA

It can be seen from Table 8.1 that the GOI made several attempts to adjust and readjust the RE selling price; in some cases revisions were made more than once. In small hydropower plants, for instance, there were at least four MEMR regulations with different electricity prices which had been revised due to inputs from related parties, adjustment for inflation, and exchange rates. From the many revisions of FIT regulation, it can be concluded that the GOI puts in a lot of effort, and thus relies on this policy, to accelerate deployment of renewable energy.

8.3 Data Acquisition

p. 150

Effectiveness is defined as 'the extent to which intended objectives are met, for instance, the actual increase in the output of renewable electricity generated or shares of renewable energy in total energy supplies within a specified time period' (IRENA 2012: 12). In this study, the effectiveness of the FIT policy is measured by the increase in deployment of renewable energy power plants over the period since the policy was made in 2010 to date (a five-year period), compared with the GOI's target for achieving its share of the national energy mix. As suggested by IRENA (2012), in analysing the effectiveness of a policy, it is necessary to conduct an in-depth analysis to elaborate factors that support or hinder the outcome of the policy, such as external factors or indirectly related barriers to the success of policy implementation.

8.3.1 Study Location

Indonesia is made up of 17,000 islands and has one of the longest coastlines in the world. Most of the regions in Indonesia, especially in the eastern part, still have very poor infrastructure conditions. However, with a population of about 300 million and relatively stable economic growth (4–6 per cent per annum over the last five years), it is a country with many interesting prospects.

Politically speaking, Indonesia can be categorized as a country in transitional democracy, because, after its independence on 17 August 1945, democratic transition did not start to happen until 1998 when the long reign of General Suharto was toppled by students' demonstrations after 30 years of authoritative governance. After the so-called reformation era, Indonesian society has undergone a drastic change, including a shift from centralized to decentralized governance. Nowadays the people of Indonesia are enjoying a new sense of democracy. This new-found freedom allows them to freely question or even disobey what the government wants. This understanding of the political situation is important in comprehending the real condition of governance related to the deployment of renewable energy power plants.

This study uses a quantitative and qualitative research approach. The quantitative study is conducted by collecting, comparing, and analysing data from various institutions related to the targeted deployment of renewable energy power plants and its realization in the field. The comparison is followed by site visits to several locations for the purpose of confirmation. Due to limited time and budget, the confirmation field surveys were only conducted in West Java, a province adjacent to Jakarta, to gain a deeper perspective from players in renewable energy in real circumstances.

p. 151

One reason for choosing West Java for site confirmation is because it is the province where the development of RE is considered to be the highest, and it has been a pioneer in RE development in Indonesia, such as in geothermal, micro-hydro, biogas, biofuel, and so on. It is densely populated with about 46 million people inhabiting some 35,000 square kilometres of land. With 6.5 per cent annual economic growth in 2012, its energy consumption has continued increasing to around 8–11 per cent for all sectors, implying that the usage of energy is still inefficient. Thus, serious efforts to lower energy consumption, as well as efforts to diversify fossil-fuel energy with more renewable kinds of energy have been conducted since 2001. Some renewable energy technologies, such as micro-hydropower plants, are considered to be relatively successful.

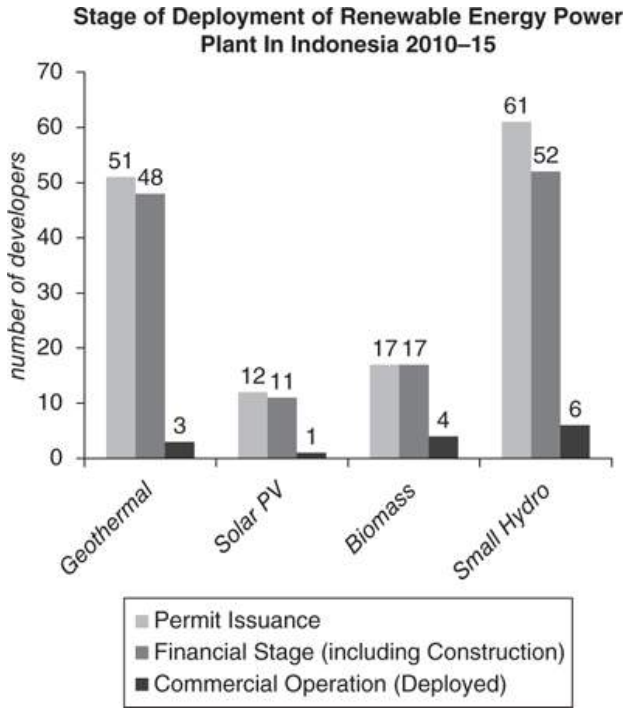
PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Downloaded from https://academic.oup.com/book/16547/chapter/172504735 by guest on 24 March 2023

8.3.2 Quantitative Data

Data analysis from several data resources (MEMR, SEC, local government) resulted in a wide discrepancy between targeted installed capacity and its realization. Most commercial RE projects have been delayed by one to five years. As has been stated before, the comparison between projected and real data for small hydro power plants is only conducted for West Java, which is considered to mirror Indonesia's condition. As per IRENA's definition (2012), deployment of renewable energy power plants includes the commercial operation of the plant, not just installation. The financial stage includes preparation of funding sources, negotiating and signing of a Power Purchasing Agreement (PPA) with the SEC, the process of obtaining various kinds of permits (from central government as well as from local government), and the construction stage, which includes land acquisition, community preparation, mobilization, and other construction activities. Meanwhile, number of permits refers to the sum of permits related with small hydro power plants, issued either by central government (SEC, DGNRE, and DGE), or local government in the form of location permits. Figure 8.1 shows the actual installed capacity and the various stages of renewable energy power plant deployment from 2010, or since the FIT implementation, until December 2015.

Figure 8.1.



Deployment status of renewable energy power plants after FIT policy.

Source: Author's data compilation from various institutions and field surveys.*Note*: For Small Hydro, data only from West Java Province.

Official data issued by central government institutions are not consistent. For instance, for small hydropower, one published report says that there are only 19 small hydropower licences in West Java, while another institution states there are 31, and yet another says 34 licences. When these data are cross-checked with data from local government (regency), the compilation from regencies which have small hydropower sites suggests there are 61 small hydropower licences in West Java.

Another interesting result of the data analysis is that, on average, only 10 per cent of permits issued for power generation from the renewable energy source, are already at the commercial operation stage or deployed. Some of the permits had been issued for more than five years. Thus, there must be some problems
p. 152 in the ↳ field that prevent the FIT policy from having a positive effect on the deployment of renewable energy power plants. To delve deeper into this discrepancy, qualitative surveys were conducted using semi-structured interviews. The identities of all those interviewed in this study, including experts, developers, and public authorities, are confidential due to the sensitivity of the issue.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Downloaded from https://academic.oup.com/book/16547/chapter/172504735 by guest on 24 March 2023

8.3.3 Qualitative Data

From the collected data and results of the analysis, an attempt to elaborate the causes of the discrepancy between projected goals and the real situation is conducted using semi-structured interviews. It is worth noting that not everyone contacted who was directly involved in the deployment of RE was willing to be interviewed, especially government officials and developers. Some were eventually willing to give information when the interview was conducted outside of their offices, some objected to the interview being recorded, and most of them agreed to be interviewed with the promise that their names would not be revealed. On average, the interviews lasted between about 15 minutes and 2 hours; some were recorded while others were field-noted.

p. 153 In total, there were 22 key respondents, consisting of 5 investors (4 small hydropower developers, 1 geothermal), 14 government officials (5 from central government, 2 from provincial government, and 7 from regency (local) government), and 3 respondents from related agencies (1 SEC, 1 expert, 1 practitioner). Table 8.2 shows a general guidance questions to semi-structure interviews conducted, which are slightly different for each group of respondents.

Table 8.2. List of guidance questions for key respondents

Guidance questions for investors/developers:
1. How has the introduction of FIT policy affected your decision to invest in RE power plant? 2. Is the current structure of FIT policy sufficient to foster deployment of RE? if not, why? 3. What obstacles do you find in the deployment of RE power plants? 4. Is there any suggestion you want to propose to overcome those obstacles?
Guidance questions for government officials (central, regional, and local government):
1. Is there any special treatment for the issuance of permits for RE investment, compared with other kinds of permits? 2. Do you know the government's target for increasing the usage of RE sources? 3. What obstacles do you find in the deployment of RE power plants? 4. Is there any suggestion you want to propose to overcome those obstacles?
Guidance questions for government officials (expert, practitioner, and utility company):
1. Is the recent structure of FIT policy sufficient to foster deployment of RE? if not, why? 2. What are the obstacles to implementing FIT policy in Indonesia? 3. Is there any suggestion you want to propose to overcome those obstacles?

Source: Author's illustration.

The analysis is focused on the evaluation of FIT policy in Indonesia: whether it is effective in increasing the usage of RE, whether there is any room for improvement, and if not effective, then what are the alternatives. For definition purposes, deployment of renewable energy means the power plant is not just already installed and producing electricity, but it also has generated income from selling electricity.

8.4 Analysis

8.4.1 Effectiveness of FIT Policy

It is interesting to note that since around 2011 when the FIT policy was first made, investment in renewable energy has been increasing significantly. However, the study results showed a totally different outcome regarding real deployment of renewable energy power plants. Take geothermal energy, for instance: from 51
p. 154 licences issued by the MEMR, only 3 are operational ↳ commercially in 2015. This means that the amount of delayed deployment of geothermal power plants exceeds 90 per cent. For solar PV and biomass, data for real deployment of power plants are not very different. For small hydropower plants, the data, which are taken only from West Java, show that the rate of successful deployment is no better, with only 6 out of 61 licences having been fully deployed commercially.

Those at the construction phase (representing a total 56.69 MW from nine companies) report that the delayed construction stage is mostly caused by difficulties in obtaining a location permit or a building permit from local (regency) government, hard negotiations of land price, and the demands of local communities. In West Java, there are no biomass (domestic waste to energy power plant), solar PV, or wind turbine power plants which are fully operational in a commercial sense. Some small MWs have been installed (solar PV and biomass), but negotiations of price and other related processes are still underway.

The 19 small hydropowers that are in the finance phase (total 88,174 MW) report several problems including difficulties in obtaining PPA with the SEC and the long process of permit issuance for surface water usage, in which the two processes are intermingled. It is interesting that policies for river usage permits, which depend on where the river is located, are different from one locality to another, and from local government to central government.

One unique example is a small hydropower plant of 600 kW in a region of Central Java, which has been fully constructed but has not been operational because it has not obtained the PPA from the SEC. And the SEC cannot issue the PPA because the related institution has not been issued with a permit for water resource utilization. There has been much confusion over who is authorized to issue the permit: initially it was thought to be the responsibility of local government, but, then it was clear that the specific watershed's authority belongs to central government (Ministry of Public Works). However, up until now the permit has not been issued by the minister, with no clear explanation.

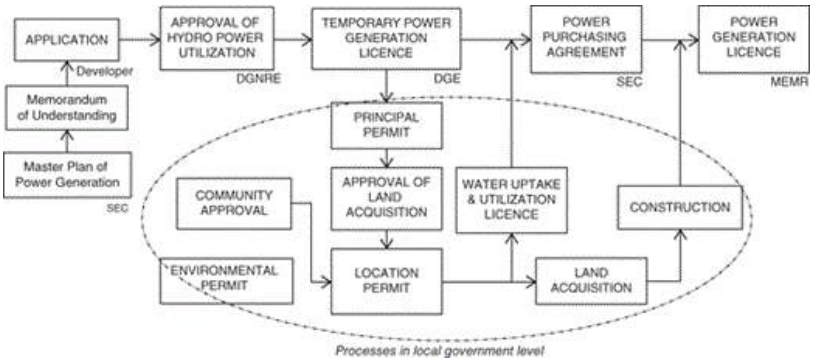
When asked whether the structure of FIT policy has met their expectations, all respondents from investors of RE power plants admitted that the structure and the selling price have been sufficient to make the project (on paper) seem viable, and this has greatly affected their decision to invest in renewable energy. Especially for small hydropower investors, who enjoy a high price of electricity and for whom the domestic content of the technology is relatively high, the structure of small hydropower has caused a surge of domestic investors who are interested in investing. This attractiveness of RE investment has been confirmed by the US Department of Commerce report (US Department of Commerce 2010) and the UNDP (United Nations Development Programme) report (UNDP 2015). However, the investors convey that, in the process of
p. 155 development, the many additional costs incurred by the many ↳ kinds of permits that have to be obtained before they are fully operational, and the long delays caused by them, have eroded the profitability of RE projects.

8.4.2 Procedure for Obtaining a Renewable Energy Licence

In delving deeper into the permit procedure, the research is focused on small hydro development in West Java only, due to limited time and budget. There is no coherent data between institutions and no transparency of information. At the lower level of government, which is provincial and regency government, this is even worse. That is why interviews were conducted covertly and some of those interviewed agreed to be interviewed only on condition that their names would not be revealed. Figure 8.2 displays the general procedure to be conducted in order to obtain a small hydropower plant licence. The flows of procedures at the lower levels of government (province and regency government) are simplified and compiled from practices existing in different regencies.

Downloaded from https://academic.oup.com/book/16547/chapter/172504735 by guest on 24 March 2023

Figure 8.2.



Procedure for the issuance of licences for small hydropower generation.

Source: Author's illustration.

The upper part of the procedure illustrates the flow of applications for power plant licences according to MEMR Regulations No 22/2010, where the developers of on-grid power generation must submit an application to the Directorate General of Electricity and must previously have had a memorandum of understanding with the SEC that the planned location of the development is already included in the Master Plan. Then, the developer must submit a deposit of 5 per cent of total investment to the Directorate General of New and Renewable Energy, in order to obtain Approval for Hydro Utilization. Thereafter, a temporary permit for small hydropower generation is issued. Based on this temporary permit, the developer must then
p. 156 go through ↳ the procedure at the lower level of government (province government and related regency government).

This is where matters get more complicated, because, in order to conduct land acquisition, the developer must go through several processes, often very tiring, with no time limit, and a lot of additional (and unofficial) cost. To make matters worse, there is no standard procedure for this land acquisition between regencies, and the process may vary greatly from one place to another. When there is forest land included in the design, the matter is even more complicated because the timeline of the procedure to obtain permission to use the land often exceeds the length of the permit.

In general, there are at least 14 kinds of licences and permits (and other permit-like processes) that have to be obtained before a developer can start the construction of a RE power plant: four from central government, one from provincial government, and nine from regency government. There are also some associated recommendations from related bodies which are a must-have requirement before a permit can be issued (this includes community approval). For geothermal investment, this number may well be higher, especially for foreign investors. It is worth noting that the costs associated with permit issuance are generally not stated clearly; sometimes they need to be negotiated, and sometimes they require much higher costs than expected. Although some RE investors admit that they have prepared for such excess costs, nevertheless the negotiation process requires time, delays schedules, and lowers the profitability of RE investments.

8.4.3 Obstacles to Deployment of Renewable Energy

8.4.3.1 Incoherent Regulations between Related Institutions

Incoherent knowledge about renewable energy, different agendas, and overlapping policies between ministries and moreover between central government and local government, surfaced several times in the elaboration of obstacles to renewable energy deployment. One provincial government official who was authorized to issue water utilization permits complained that the MEMR issued a permit to build small hydropower without stating the exact location, with the result that local government, in certain areas of West Java, issued two permits for one exact same location. This disturbs the steady flow of the river and potentially could conflict with rice field irrigation. He then questioned whether the river discharge usage permit should come before or after a small hydropower plant permit is issued by the MEMR. However, when questioned about this problem, the regency government official seemed not to recognize this problem, stating that they only process location permits as they are proposed, and that there is no clarification
p. 157 process with the higher level of ↳ government or with related institutions whatsoever. Thus, if there is overlapping of location permits, it is not their problem.

The institutional problem becomes worse when an RE power plant is to be built in a conservation or protected forest area because the clearance and permit to use the forest area must come from the Minister of Forestry. Even though they know that renewable energy plants would not damage the forest (unlike mining, for instance), still there is no special treatment for the so-called sustainable energy and non-sustainable usage of the forest. Even though, recently, there has been a revision for geothermal energy that enables protected forest to be used for geothermal power plants, a geothermal investor respondent still complained that the issuance of the permit is long and complex.

8.4.3.2 Long Process of Electricity Purchasing

Investors also convey that the signing of a PPA with the SEC is extremely complex and technical and bargaining is tough. Sometimes the process took longer than a year. A geothermal power plant investor stated that he has to wait four years before the agreement is reached. Another investor even suspects that the SEC is reluctant to buy electricity from renewable energy sources because it then has to cover additional costs compared to when it uses coal-fired power plants (personal interviews, August–September 2015).

Meanwhile, in reply to questions about the many difficulties experienced in obtaining PPAs, the Director of Business Ventures of the SEC (personal interview, September 2015) denied that the SEC is reluctant to buy electricity from RE sources, stating that it is mandatory for the SEC to buy in accordance with the MEMR regulations. However, as a state-owned company, there are several requirements that have to be met before issuance of a PPA including, among others, obtaining all related permits, land clearance, and agreement with the local community. In reply to questions about the profitability of trading electricity from RE sources, she admitted that the price is considerably higher than coal-generated electricity (average production cost of around US$0.5). At present, the buying price of electricity from RE varies between US$0.10 and US$0.17, which is sold to the public at an average price of around US$0.8 to US$0.9, and this makes the discrepancy in cost a burden for the SEC to cover from elsewhere.

Another complaint from the SEC is that while they have to pay instantly the electricity price as generated, reimbursement from the government is dependent on the national budgeting agenda. Reimbursement is sometimes delayed for several months and sometimes is not provided at the exact amount that has been disbursed by the SEC. Thus, she proposed that there should be an independent agency to manage the financing of electricity from RE sources which deal with the electricity price negotiations, payments of
p. 158 power purchasing, and all related matters. Learning from the case of Malaysia and Thailand, this ↳ agency would ensure that the discrepancy in cost between the average production cost and the selling price from conventional power plants, which is reimbursed in the form of government subsidy, can be managed effectively without depending on political processes in the annual national budgeting agenda.

REPUBLIK INDONESIA

Downloaded from https://academic.oup.com/book/16547/chapter/172504735 by guest on 24 March 2023

8.4.3.3 Problems with Community and Land Acquisition

Another factor that hinders speedy deployment of RE power plants is that in some locations the community does not wish to sell its land due to lack of knowledge about renewable energy. This is especially true for geothermal energy, where in West Java at least, there are four locations where geothermal plants are delayed due to various kinds of conflict. Yuliani (2013) stated that community resistance in many locations of geothermal development in Indonesia represents the major obstacle to renewable energy deployment. Similarly, Hasan and Wahjosudibjo (2014) suspected that there are several issues other than the electricity tariff that have to be addressed by the government in order to improve geothermal power plants.

It is worth noting that, after some 30 years of relatively authoritarian governance, since around the 2000s, the Indonesian people have been enjoying a more democratic atmosphere in what is called the reformation era, where governance is more decentralized, public policy is more bottom-up and participatory, and there is a new-found freedom of speech among the people. Yuliani (2013) noted that this new condition in a community sometimes brings problems for the development of infrastructure, especially when there is no sufficient preparation for the community to accept new things, such as renewable energy technology. Even respondents from local government officials (regency government) show that this lack of information is not only true for the layman but also for bureaucrats.

In the deployment of small hydropower plants, community conflicts are usually about the amount of water used for irrigation, which mostly can be solved by good communication. However, unavailability of a standard price for land, especially in remote areas, often delays the land acquisition process and if the price wanted by the community exceeds the expected figure this can lower the economic viability of the project. It is worth noting that, for the foreign investor, this problem of the price of land skyrocketing may worsen, and needs to be carefully considered.

8.4.4 Miscellaneous: Unanticipated Impacts of FIT Policy

The significant increase in renewable energy investment, especially for small hydropower, creates several
p. 159 unanticipated impacts which are not always positive. ↳ Government officials, as well as developers, report that there is some kind of rivalry between institutions related to the importance of their role in permit processes. The struggle to acquire the most profitable sites for hydropower plants has created a situation where power plants are located very near each other. On the supply side, it is a worrying situation, because there is no capacity cap that limits how much of the generated electricity the electricity company is willing to buy.

Related to land acquisition, a growing number of people play the role of a land realtor, hoping that they can benefit from discrepancies in land prices. This, in turn, makes the price of land uncontrollable in some regions. One developer complained that government officials are also players in land acquisition deals.

Before the implementation of FIT, small hydropower was used to electrify communities in remote regions, usually with aid from the government. However, with the massive emergence of hydro investors and the fight for the best locations, these community-based small hydropower plants are left behind. In West Java, there are at least two locations where micro-hydro plants were ready to be constructed but eventually failed because the power plant licence for the exact location had been issued by the MEMR.

8.5 Conclusion and Recommendations

8.5.1 Conclusion

Indonesia is an example of a country where FIT policy, which is considered quite successful in developed countries, is duplicated without careful considerations of the existing sociopolitical conditions. The FIT policy in Indonesia, which has been formulated in eight ministry regulations (four original versions and five revised versions) has not significantly improved deployment of its renewable energy. It is true that investment interest in renewable energy has soared to a level which has never been seen since its implementation around the 2010s. However, data confirmed through field reports shows that about 90 per cent of scheduled deployments of renewable energy power plants are delayed, and targets are far from realized.

Downloaded from https://academic.oup.com/book/16547/chapter/172504735 by guest on 24 March 2023

Many complaints related to difficulties in obtaining a PPA, lack of a guarantee of grid connection, and complex contract structure, indicating that some of the FIT policy principles are not being met, although the price of electricity is satisfactory. The study also reveals several other issues that pose obstacles to renewable energy deployment, which can be grouped into three big problems: unclear and inconsistent policies both horizontally (between ministries) and vertically (between levels of government), the complex
p. 160 requirements of many permits, and difficulties related to land acquisition which includes conflict with ↳ the community. Adding to those problems in the field is the corrupt behaviour in permit issuance processes, which has made the calculation of the economic scale of a project difficult.

To sum up, the FIT policy when applied in a less developed country such as Indonesia must work in tandem with other efforts. The complex structure of governance, lack of community knowledge about renewable energy, and incoherent coordination between related institutions, all add up to difficulties of implementation in the field. If Indonesia is serious about achieving its projected goals for renewable energy deployment, then efforts must be strengthened and calculated measures must be taken. On the other hand, the study also underlines the importance of narrowing the wide gap in transitioning to cleaner energy, where less developed and developed countries both face very different challenges.

8.5.2 Recommendation

In order to enhance the effectiveness of FIT policy in increasing the success of renewable energy deployment, it is recommended that the GOI simplifies the licence procedures, either at the central government level or most especially at the local government level. This will require an exceptionally strong commitment from all parties, because every institution holds to its own laws and regulations, and may not have the same agenda for the development of renewable energy.

The existence of specific budgets allocated for renewable energy subsidies, as implemented by many countries, can play a significant role in lessening the burden of developers. The subsidy which is intended to pay for the discrepancy of production costs between renewable energy and conventional power plants has to be independently managed, and not be dependent on the political process in the national budget planning which is decided annually. One realistic option is to form an independent body which is given the mandate to facilitate the permit process, formulate and finalize PPA, and manage various aspects related to pricing and payments of the government subsidy for renewable energy.

It is also recommended that the GOI should not abandon community-based efforts in renewable energy deployment. The excessive focus on investment to boost renewable energy deployment is not sustainable because it does not create a sense of belonging from the surrounding community. On the other hand, there is a lot of under-utilized renewable energy potential which is most suitable to be used for domestic energy, such as biomass.

8.5.3 Suggestions for Further Research

Due to the limited time and budget for conducting this field survey, in-depth investigation of locations for
p. 161 the deployment of renewable energy power ↳ plants has only been conducted at a limited number of sites. It is suggested that a thorough assessment is conducted in other parts of Indonesia, including of all kinds of renewable technologies. Field practices at the lower level of government may vary from place to place. Thus, a comparison between regions is recommended in order to obtain a general description of how permit procedures are carried out at local government level, and eventually, to suggest the best option for simplifying procedures and increasing the effectiveness of deployment. There are at least two small hydropower plants which are said to have been operational in published reports by related institutions; in reality, they are still in the process of becoming fully operational commercially. Thus, it is best to check the location of development on the site to assess the real situation, especially for solar PV and biomass power plants which are located in remote areas of Indonesia.

The availability of low-interest loans dedicated to renewable energy development from various banking and financial institution, both national and international, must also be scrutinized. The fact that about 90 per cent of power plant licences have not shown any progress after several years, raised some concerns about prejudice from several of those surveyed that the licences are used to obtain loans to be invested elsewhere. In this study, the researcher does not have access to any banking personnel and, under the bank privacy

Downloaded from https://academic.oup.com/book/16547/chapter/172504735 by guest on 24 March 2023

principle, it could be difficult to get any information. However, in order to create a healthy investment climate for renewable energy, it is suggested that measures are taken to ensure that renewable energy loans are used appropriately.

Abstract: The utilization of lignocellulose biomass as an alternative source of renewable energy production via green technology is becoming important, and is in line with sustainable development goal initiatives. Lignocellulolytic bacteria, such as *Bacillus* spp., can break down biomass by producing hydrolytic enzymes, which are crucial in the successful conversion of biomass or lignocellulosic material into renewable energy. This information gave rise to this study, where municipal solid waste sediments of a sanitary municipal solid waste landfill were sampled and screened, and lignocellulolytic bacteria were isolated and characterized. Samples were taken from four different locations at the Pulau Burung landfill site in Malaysia. Lignin and starch were used as sources of carbon to identify potential bacteria that exhibit multi-enzymatic activity. The growth rate and doubling time of bacterial isolates in lignin and starch were taken as the criteria for selection. Eleven bacterial isolates were screened for cellulase activity using iodine and Congo red dyes. The cellulase activity of these isolates ranged from 0.8 to 1.7 U/mL. We carried out 16S rRNA gene sequencing to identify the phyla of the selected bacterial isolates. Phylogenetic analysis was also conducted based on the 16S rRNA sequences of the bacterial isolates and related Bacillus species, and a tree was generated using the Neighbor-Joining method. In this study, *Bacillus proteolyticus*, *Bacillus Sanguinis*, *Bacillus spizizenii*, *Bacillus paramycoides*, *Bacillus paranthracis and Neobacillus fumarioli* were identified as promising bacteria capable of expressing lignocellulolytic enzymes and degrading the lignocellulosic biomass present in municipal solid waste.

1. Introduction

The continuous rise in the global population and fast industrialization and urbanization have shown direct impacts on the production of municipal solid waste [1]. Municipal solid waste (MSW) has become a serious concern in the developing and least-developed nations, where adequate waste collection facilities are not available [2]. Approximately two billion metric tons of urban solid waste are currently generated at the global level, and this is expected to double by the year 2050 [3]. The disposal methods of municipal solid waste are not well planned globally, and this waste has become a major environmental threat

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

during the past few years [4]. Landfills have been adopted as a major means of disposing of municipal solid waste in both industrialized and developing countries [5]. Municipal solid waste disposal into landfill sites has had deleterious impacts on aquatic ecosystems and the health of human-beings due to its offensive odor, leachate leakage and toxic gas emissions [6–9].

The high demand for energy, together with the fast depletion rate of fossil fuels, is gaining global attention [10]. The energy transition is an important step towards carbon neutrality, and it is beneficial for developing countries in terms of environmental protection and the economy [11]. There is a need to move from fossil fuels to renewable energy sources to achieve the energy transition to low carbon generation. The waste disposal and energy crisis problems can be mitigated by exploiting lignocellulosic biomass, which is readily available at zero cost as a renewable resource [12]. Lignocellulose is a widely available and unexploited source, as around two hundred billion tons of lignocellulose are generated annually all across the globe [13]. Lignocellulose biomass consists of agricultural and forestry residues, yard trimmings and energy crops, which are made up of cellulose, hemicellulose and lignin and form a predominant part of the green waste fraction of municipal solid waste (MSW). Approximately 50 and 12% cellulose and hemicellulose, respectively, are present in residential municipal solid waste in the form of dry weight [14]. Lignocellulosic materials have become a major feedstock for biofuels because the presence of multi-carbon components and their derivatives can be transformed into value-added materials for the syntheses of sugar, alcohol, lipids, etc. [15,16]. Various physical and chemical methods have been applied in lignocellulose bioconversion, but due to their high costs, use of toxic chemicals, and complicated and expensive procedures, their processes are economically infeasible, and thus, these strategies have not been successful. The biodegradation of lignocellulose biomass by microbial enzymes is a promising and sustainable approach, as microbes can simultaneously perform the role of pre-treatment and easily break down lignocellulosic components [17]. Different types of enzyme, such as ligninolytic, cellulolytic and hemicellulolytic enzymes, can be applied in lignocellulose biodegradation [18]. Poszytek et al. [19], in 2016, reported greater efficiency of microbial lignocellulolytic enzymes for bioconversion compared to commercial enzymes. The individual microbial strains or consortia secrete hydrolytic enzymes during their metabolism and degrade cellulose, hemicellulose and lignin into smaller fragments [20]. A number of previous studies revealed that an anaerobic environment, such as the bovine rumen, and the elephant and termite gut, acts as a potential source of lignocellulose-degrading enzymes [21,22]. Such environments harbor microbial communities that convert lignocellulosic biomass without pre-treatment and are currently applied in commercial processes. The composition of leachate and sediment at landfill sites depends on different factors, such as the age of the landfill, its waste composition, its temperature, etc. [23]. The structure of a microbial community is also affected by the age and composition of the landfill.

Bacteria are considered potential candidates for industrial applications due to their fast growth, the presence of abundant enzymes, their pressure resistance and their ease of genetic manipulation to achieve improved properties [24,25]. Bacteria are prolific producers of cellulase and are extracellularly secreted in huge amounts. Cellulase is considered the black box of lignocellulose degradation, and utilizes the homogeneous property of cellulose by hydrolyzing β-1, 4 glycosidic linkages [26]. Various types of cellulose may incite bacteria to generate different types of cellulase and make microbes specific to lignocellulosic materials [27]. *Bacillus* is a potential genus of bacteria which significantly generates cellulase enzymes [28,29]. *Bacillus coagulans*, *Bacillus subtilis*, *Bacillus licheniformis* and *Bacillus cereus* reflected high cellulolytic activity for lignocellulosic substances [30]. Balla et al. [31], in 2022, reported high cellulolytic activity in bacterial communities across different ecosystem, and observed that bacterial species were able to produce enzymes that can hydrolyze cellulosic substrates present in both soluble and insoluble states. Cellulase is composed of endoglucanases, exoglucanases, and β-glucosidases, which act in a synergistic way to hydrolyze the lignocellulosic biomass [32]. The endo-β-1, 4-glucanase and exo-β-1,4

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

cellobiohydrolase degrade cellulose into cello-oligosaccharides, which are then hydrolyzed to glucose by β-glucosidase [33].

Landfill sites are heterogeneous in nature, comprise mainly lignocellulosic material and can be considered ideal sites for biomass conversion. However, landfill sites have not been extensively explored and studied [34]. Studies have confirmed that *Bacillus* spp. secrete enzymes for lignin and cellulose degradation, metabolize dioxane lignin and break the biphenyl structures of lignin. *Clostridium*, *Cellulomonas Rumminococcus*, *Alteromonas*, *Acetivibrio, etc.* are other bacteria that have been reported to exhibit cellulolytic activity. Due to their fast propagation, convenient molecular genetics, protein expression with a smaller genome and high adaptability towards harsh environmental conditions, bacteria are suitable candidates for the degradation of lignocellulosic biomass [26]. Yong et al. [35], in 2019, reviewed the status of municipal solid waste in Malaysia and reported that the application of MSW in energy generation may promote growth and sustainable development in Malaysia. To the best of our knowledge, no reports are available in the literature regarding the isolation and characterization of potential bacteria and their application in lignocellulose biomass conversion at the Pulau Burung landfill site in Malaysia. Therefore, we were interested in finding potential candidates that can efficiently degrade the cellulose and hemicellulose contents of the lignocellulosic materials present in MSW. The main objectives of the present investigation were: (i) the extensive characterization and identification of lignocellulolytic bacteria present at the Pulau Burung landfill site in Malaysia and their comparison with the existing literature data; (ii) the screening of multi-enzymatic bacteria that will make them more suitable in lignocellulose-driven refinery; and (iii) the generation of information and recommendations for designing future consortia for the complete degradation of lignocellulose.

2. Materials and Methods

2.1. Sampling and Physico-Chemical Characterization of Waste Samples

Sediment samples were collected from the Pulau Burung sanitary landfill site (5°19.36; 100°42.67′ E) located in Nibong Tebal, Penang, Malaysia, on 7 March 2020 at 9:45 a.m. The collected samples were transported to our laboratory as per the standard procedures described by Forster [36] for physico-chemical and microbiological analysis.

Sampling was performed during the rainy season in March 2020 from four different randomly selected sites at the Pulau Burung sanitary landfill, namely A, B, C and D, at a depth of 20 cm. The temperature was measured in situ at each site using a digital thermometer (Rapitest, Kuala Lumpur, Malaysia). Samples were kept at 4 °C until analysis.

pH was measured in the laboratory using the standard method described by Radojevic and Bashki [37]. Twenty grams of sediment that was free from larger materials was placed in a beaker. Forty milliliters of distilled water was mixed, and contents swirled and allowed to stand for 30 min. The pH was analyzed by using a pH meter (Mettler-Toledo, Zurich, Switzerland) by ensuring that the electrode did not touch the settled sediment particles but remained in the supernatant liquid above while the reading was taken. This prevented errors in the readings [37].

2.2. Isolation and Identification of Bacteria

2.2.1. Isolation of Potential Bacteria

Bacterial species were isolated as per the method of Reynolds [38]. The samples were serially diluted by weighing 1 g of sediment and diluting it tenfold. Afterwards, 0.1 mL of dilutions from each fold were dispersed on the sterilized nutrient agar plates and incubated at 37 °C for 24 h. The clear colonies were sub-cultured several times to ensure purity. The various colonies observed were sub-cultured using the streak plate method until pure colonies were obtained. The morphologies of the colonies were observed; those with similar morphologies were considered the same, and distinct ones were further sub-cultured to obtain pure colonies. Pure colonies were stored at 4 °C on nutrient agar slants for further analysis.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

2.2.2. *Preliminary Identification of Potential Bacteria*

After the isolation of bacteria, morphological and biochemical characterization was conducted using standard procedures described in *Bergey's Manual of Determinative Bacteriology* for the identification of potential bacteria [39]. Morphological characterization was performed based on visual appearance and Gram staining using the method described by Smith [40].

2.3. Screening for Ligninolytic and Cellulolytic Ability

Predictive modeling was used to check the growth rate of microorganisms. This was measured by taking aliquots at intervals while growing the microbial culture [41]. The bacterial isolates were inoculated into pre-prepared sterilized media containing starch and lignin as the sole sources of nutrients. The composition of the media used is stated in Table 1. They were prepared to determine the lignocellulolytic ability of the bacterial isolates.

Table 1. Screening media composition.

	Deionized Water (mL)	**Sole Carbon Source (g)**
Lignin	10	0.1
Starch	10	0.1

The absorbance was taken at 600 nm using a Hach DR 2800 spectrophotometer (Hach Malaysia, Kuala Lumpur)hourly for up to 24 h. The results were used for kinetic growth studies of the bacterial population.

2.4. Kinetic Growth Studies for Ligninolytic and Cellulolytic Ability of Isolated Bacteria

Using the results from the screening (2.3), growth curves were derived and used to calculate growth rate and doubling time for each isolate. Mathematical modeling was used to fit the results obtained for bacterial growth curve prediction [42]. A positive fit indicated bacteria growth (G), while a negative fit was an indication of non-bacterial growth (NG). The coefficient of determination (R^2) was applied to analyze the efficiency of model. An R^2 value close to 1 indicated that the method is reliable for predicting the growth profile of the isolated bacteria.

To obtain the growth rate of the isolates, individual growth curves were processed by retrieving sequential sets of n data values, where n was in the range of 3 to 10, as previously described by Breidt et al. [43] in 1994. The slope of the line (I) was used to derive the growth rate, and the maximum slope is the specific growth rate. Values with higher R^2 were preferred, as they were more indicative of growth rate. Equations (1) and (2) as seen below depict the formula used for the kinetic studies:

$$Y = \mu \times Yo \quad (1)$$

μ = Growth rate

The formula for population growth rate, and duplication time is shown below:

$$TD = \frac{\ln 2}{K} \quad (2)$$

Doubling time (TD)

ln2 = Neperian logarithm of 2

k = Growth rate

REPUBLIK INDONESIA

2.5. Enzyme Assays

2.5.1. Qualitative Screening for Hydrolytic Enzyme Production

Upon completion of the kinetic studies, isolates that showed great potential in utilizing both lignin and starch were subjected to qualitative assays to test for xylanase, protease, amylase and cellulase. This potential was measured by comparing the growth rate (μ) in each medium with isolates that had better growth rates. For the specific isolation of cellulolytic microorganisms, CMC agar plates were prepared using the following composition: agar powder: 15 g, yeast extract: 1 g, CMC: 3 g, $FeSO_4.7H_2O$: 0.01 g, $(NH4)_2SO_4$: 1 g, NaCl: 2 g, $MgSO_4.7H_2O$: 0.2 g and KH_2PO_4: 1.36 g [44]. The plates were incubated at 37 °C for 3–5 days. Once single colonies had been observed, subsequent plates were split into quadrants. Colonies were placed in the middle of each quadrant and incubated once more.

For hydrolysis testing, the plates were flooded with freshly prepared Gram's iodine (2 g potassium iodine in 1 g of iodine dissolved in distilled water). The plates were read immediately, as the clear zone around the bacterial colony showed that hydrolysis was taking place. Positive plates gradually hydrolyzed the iodine until the plate became clear, whereas negative plates were unable to produce a clear zone around the bacterial colony, which reflected that there was no hydrolysis [44].

For the estimation of xylanase activity, colonies in the quadrants were flooded with Congo red (0.1% *w/v*), and then, de-stained with sodium chloride (0.1 M). The colonies that had clear zones around them were positive for xylanase, while those without it were considered negative.

To test for proteolytic ability, skimmed milk agar was prepared using the following composition: skimmed milk powder: 2.8 g, casinenzymic hydrolysates: 500 mg, yeast extract: 250 mg, dextrose: 100 mg and agar: 1.5 g (added to distilled water (100 mL) to make 1% skim milk agar). The agar plates were divided into quadrants, and isolates of interest were incubated and observed for 72 h, as per the method of Masi et al. [45]. Microbes that were able to grow showed proteolytic ability and formed halos around the colonies.

2.5.2. Quantitative Screening for Cellulolytic Ability of Microorganisms

The enzyme activity of cellulase for the DH13, DG6, AB7 and A3 strains was assayed by reducing the sugar content by Dinitrosalicylic acid [46]. These isolates were chosen because they showed enzyme activity for all qualitatively measured enzymes. Absorbance was measured at 540 nm and an enzyme unit (U) was expressed as the enzyme amount that released 1 μmol of glucose equivalent from carboxymethylcellulose.

2.6. DNA Extraction and Molecular Characterization

The DNA from pure isolates was extracted using a Vivantis DNA kit (Vivantis, Selangor, Malaysia), as per the standard method of Yi et al. [47]. The isolates were grown overnight in nutrient broth and kept in a shaker at 150 rpm and 37 °C. The obtained DNA was amplified through a polymerase chain reaction (PCR) using the universal DNA forward primer Eubac27F (50-AGAGTTTGATCCTGGCTC AG-30) and reverse primer 1492R (GGTTACCTTGTTAC GACTT-30) to target bacterial 16S rRNA. The PCR had the following protocol: 3 min at 95 °C for 32 cycles, 1 min at 94 °C, 1 min at 56 °C, 2 min for 72 °C, and 10 min for 72 °C with 4 °C intervals. After sequencing, the obtained sequences were blasted using the online tool NCBI Blast.

Phylogenetic Analysis

After blasting, the GenBank database was used to compare the 16S rDNA sequences with similar sequences. The phylogeny of the bacterial strains was constructed using Molecular Evolutionary Genetics Analysis (MEGA) software.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

2.7. Statistical Analysis

All the experiments were carried out in triplicate and data obtained in the form of mean ± standard error. Data were subjected to a two-factor analysis of variance (ANOVA) test using Microsoft excel, with significance levels of $p < 0.05$.

3. Results and Discussion

In the present investigation, sediment samples were collected from the Pulau Burung sanitary landfill in Penang, Malaysia, as shown in Table 2.

Table 2. Sampling location and condition of sediment samples collected from the Pulau Burung landfill.

Sampling Point	Latitude	Longitude	pH	Physical Appearance of Sediment	Temperature, °C
A	N5°12′6.9″	E100°25′24.7″	5.97	black	32
B	N5°12′14.8″	E100°25′33.8″	6.32	red	35
C	N5°12′7.6″	E100°25′26.3″	6.3	brown	36
D	N5°11′57.7″	E100°25′36.0″	6.9	loamy	28

pH gives an indication of the acidity or alkalinity of an environment and helps in understanding environmental interactions. The pH ranged from 5.97 to 6.9; site A showed the lowest and site D reflected highest pH, as seen in Table 1. The average pH was 6.37, which was close to the pH reported in earlier landfill studies conducted in Malaysia. pH is an important factor as it affects the possible outcome of any pretreatment process used. It has been observed that lower pH favors the hydrolysis of hemicellulose, and higher pH enhances the hydrolysis of lignin components [48].

The temperature was in the range of 28–36 °C; the site D had lowest, whereas site C had highest temperature. The average temperature was 32.8 °C. Temperature affects reactions in the environment and can amplify odor at a landfill site [49]. The variation in physio-chemical properties is due to the heterogeneity of the waste materials that are disposed of in the landfill. Saha et al. [50] reported that with increasing temperature, various gases, such as ammonia and methane, also generated.

3.1. Identification and Isolation of Bacteria

In total, 169 isolates were obtained based on the morphological characterization. A total of 37 cultures were isolated from sample site A, 34 from sample site B and 43 from sample site C, and a maximum of 55 were isolated from sample site D.

The isolates were visually and microscopically observed for characterization purposes. The Gram staining results and details of the colony features of the bacteria are highlighted in Table 3, and Figure 1 shows the appearance of some isolates after Gram staining.

These results reflect that 30% of the isolates were Gram-negative with varying shapes and arrangements (Figure 1b,c), whereas the other 70% were Gram-positive, as seen in Figure 1a,d. Our results are consistent with the findings of Zhai et al. [51] where the proportion of Gram-positive bacteria was greater compared to that of Gram-negative bacteria.

3.2. Screening for Lignocellulolytic Ability and Kinetic Studies

The isolates were tested to evaluate their ligninolytic and cellulolytic properties. The isolates were introduced into media containing either lignin or starch to analyze which isolate could grow with only one of these as a carbon source. The results reflected that out of the 169 isolates, only one isolate was unable to grow in either lignin or starch. Only 44 isolates could grow in either of the nutrient sources, so the kinetic studies focused on the 124 isolates that could grow in both lignin and starch (Supplementary Materials Table S1).

With the screening results, the growth curves, as seen in Figure 2, were derived to calculate the growth rate and doubling time for each isolate. The study of microbial growth

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

curves is an integral part of predictive microbiology and is used in various fields, as it allows for the integration of statistical, mathematical and microbiological principles in quantifying a microorganism's behavior [52]. In the modeling of bacterial growth kinetics, the behavior of a microorganism can be described under specific environmental conditions [42]. In this case, the bacterial isolates were grown in the same media of starch and lignin as sole sources of carbon, and incubated under the same conditions at 37 °C.

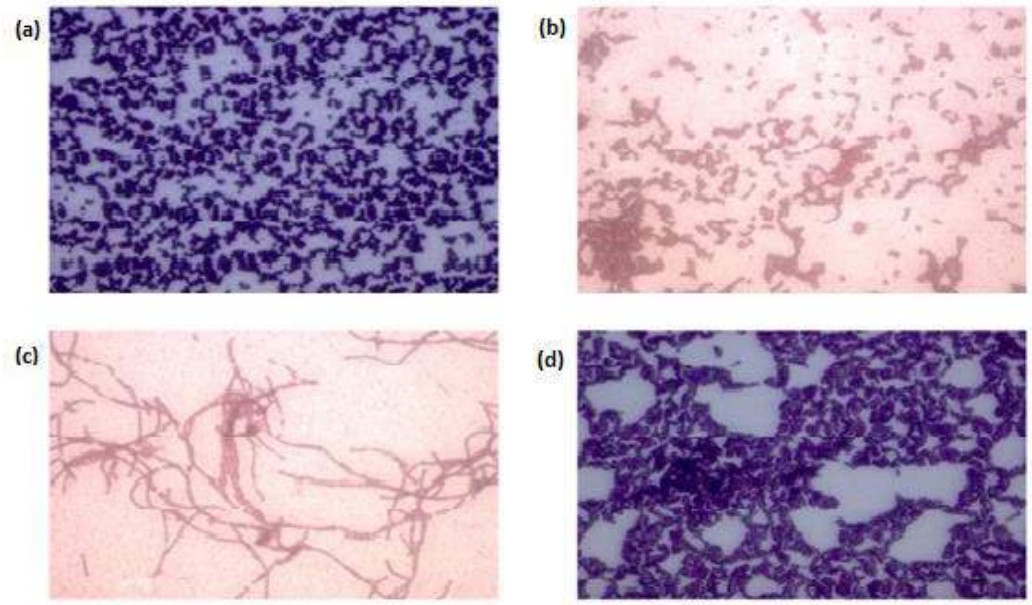

Figure 1. Gram staining of isolates for morphological identification. (**a**,**d**) Purple-colored Gram-positive bacterial isolates; (**b**,**c**) pink-colored Gram-negative bacterial isolates.

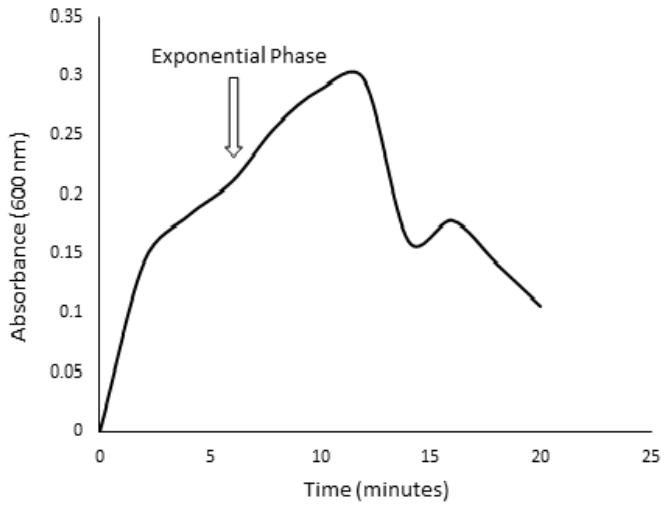

Figure 2. Growth Curve of a typical bacterial isolate from the experiment, showing the exponential phase, which was used to derive the data sets and growth rates.

The results obtained were fitted; a positive fit was likely an indication of bacterial growth, whereas a negative fit was an indication of non-bacterial growth. From the correlation equation, the growth rate was derived, and then, the doubling time (TD), which refers to the time it takes for the bacterial population to double during the exponential phase, was also derived. Only the isolates that showed a positive growth rate were taken into consideration, and their doubling time was also determined. The slope of the line (I) was used in determining the isolates' growth rate, and maximum slope connotes the

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

specific growth rate, which is depicted in Figure 3. The results are summarized in Table 3. Dey et al. [53] reported that there is a decrease in the duration time as the growth rate increases.

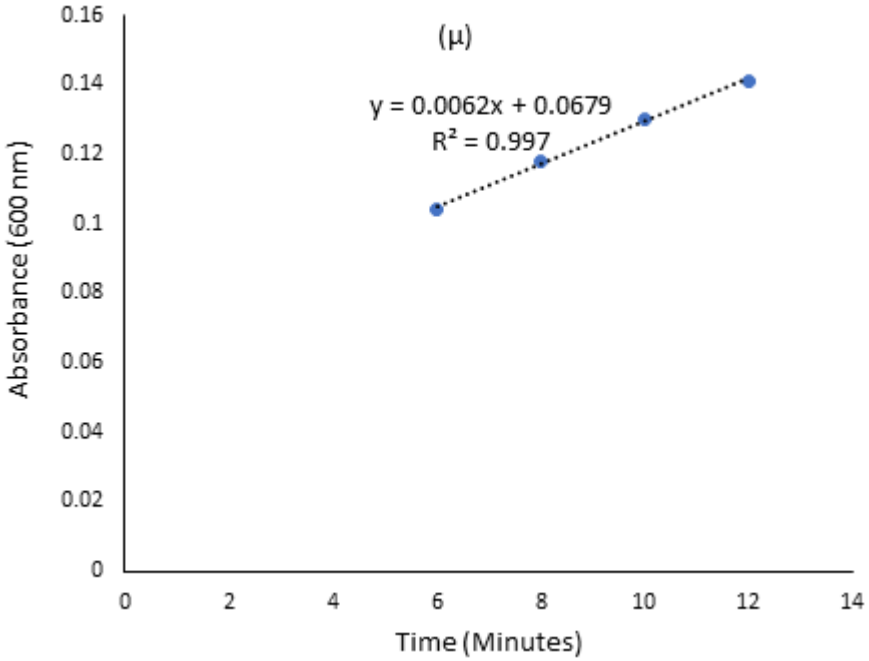

Figure 3. Slope of the growth curve showing the maximum growth rate of a typical bacterial isolate from the experiment.

In total, 61 of 124 isolates showed a positive fit and indicated the growth of bacteria. DG6 had a maximum growth rate with both lignin and starch and a doubling time of 60 min, with R^2 values of 0.9083 and 0.8613. A8 showed a high growth rate in both media with R^2 values of 0.8266 and 0.9046 in lignin and starch, respectively, whereas DH13 reflected high R^2 values of 0.9231 and 0.9173. There were some isolates that showed better growth rates in one medium than in the another. For instance, CE11 and CE3 had doubling times of 70 and 69 min in starch but 133 and 462 min in lignin, respectively. The doubling time for BC5 was 13 min in lignin and 102 min in starch media.

From the isolates that were studied for their ability to grow in both substrates, a total of eleven isolates were chosen for further studies, as they had strong growth rates and doubling times in both media. Sites A and D had five and four isolates, respectively, while site C did not have any isolates and site B had only two isolates. These results are in agreement with a metagenomic study of this landfill site that showed that site D was the most diverse in terms of identified bacteria [54]. These isolates were chosen for further assay studies and molecular characterization.

REPUBLIK INDONESIA

3.3. Enzyme Assays

The hydrolytic abilities of the bacterial isolates are given in Table 4. The result of the qualitative test on proteolytic bacteria in skim milk medium showed that out of the 11 bacteria isolates, 5 bacteria showed clear zones and 6 did not. In total, five isolates, i.e., A19, A6, AB7, DG6 and DH13, were positive for proteolytic activity. In the test for amylase-positive and -negative species, (++) was used to connote a strong positive reaction for starch hydrolysis, (+) for a positive reaction for starch hydrolysis, and (−) for a negative reaction for amylase hydrolysis.

Table 4. Results of hydrolytic assays of bacterial isolates.

Isolate	Amylase	Cellulase	Xylanase	Protease
A3	++	+	+	+
A4	+	−	−	−
A6	+	−	−	+
A8	+	−	−	−
DH31	++	+++	+++	−
AB7	+	+	+	+
BC5	+	+	+	−
DG6	+	++	++	+
DG21	+++	−	−	−
BD25	−	+++	+++	−
DH13	+	+++	+++	+

BD25 is the only isolate that had a negative reaction; DH13, DG6, BC5, AB7, A4, A6 and A8 all had positive reactions, while A19, DH31 and DG21 had strong positive reactions, with the maximum reaction occurring in DG21. In terms of cellulase and xylanase activity, seven showed positive reactions and four showed no reaction at all. Bacterial isolates such as A19, AB7, BC5 and DG5 showed the lowest reactions, DG6 had a slightly higher reaction compared to these four, but DH31, BD25 and DH13 showed highest reactions. The results were the same for both cellulase and xylanase.

The cellulase enzyme activities for the four selected isolates, DH13, DG6, AB7 and A19, were 0.876, 0.931, 1.345 and 1.768, respectively. Based on the results, A19 showed the highest activity, while DH13 showed the lowest. These results are similar to a study conducted by Guder and Krishna [55] in 2019, where cellulase enzymes ranged from 0.119 to 1.6. The authors also concluded that cellulase activity is dependent on the bacterial species.

3.4. Molecular Characterization and Phylogenetic Analysis

Phylogenetic analysis was performed using the results obtained from the 16S rDNA sequencing to allow for the proper identification of promising bacteria due to their enzymatic abilities, as described in this study. The analysis was performed in this way so that the bacteria could be matched to those already existing in the Genbank and to allow them to be maximally identified.

The results show that *Bacillus* strains were the most promising strains identified in this study, and the phylogenetic trees are reflected in Figure 4 and Table 5. *Bacillus* has been identified as an organism capable of withstanding environmental stress and has the simplest nutritional requirements for growth. It is thermophilic in nature and is known to produce hydrolytic enzymes such as α-amylase and protease [56]. The strains identified in the present study include *Bacillus proteolyticus*, *Bacillus Sanguinis*, *Bacillus spizizenii Bacillus paramycoides*, *Bacillus paranthracis and Neobacillus fumarioli.*

Neobacillus fumarioli, formerly *Bacillus fumarioli*, is a thermophilic and aerobic endospore-forming bacteria [57]. *Bacillus paranthracis and Bacillus paramycoides* exhibit bactericidal properties and are used in the mitigation of drought problems [58]. *Bacillus proteolyticus* produces protease and has been used in bioremediation and as a probiotic agent [59]. Three isolates, A6, BD25 and DG21, were identified as *Bacillus paramycoides*. They showed various

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

responses, with DG21 having higher expression of hydrolytic activities. Our findings that show the strongest positive reaction occurring for amylase enzymes agree with [60], where a bacterial isolate was optimized for amylase production and was identified as *B. paramycoides*.

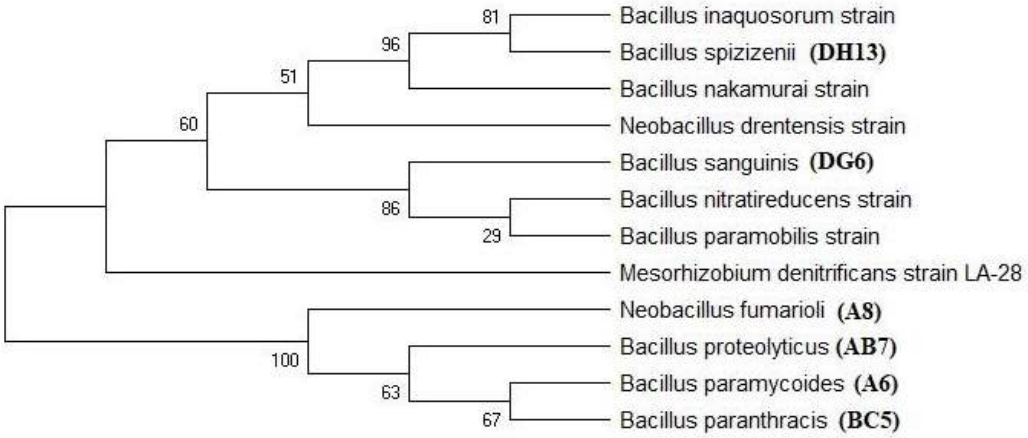

Figure 4. Phylogenetic analysis based on partial 16S rRNA sequences of the bacterial isolates and related *Bacillus* spp. The tree reconstruction was generated using the Neighbor-Joining method.

Table 5. Culture-based and molecular identification of *Bacillus* strains using 16S rRNA gene sequences obtained from waste samples.

Sample ID	Coverage	Similarity	BP	Accession	Matched Bacteria from NCBI
A6	98	99.91	1160	OQ288926	*Bacillus paramycoides*
DG6	96	98.81	2322	OQ288927	*Bacillus Sanguinis*
A8	91	97.11	1270	OQ288921	*Neobacillus fumarioli*
DG21	92	99.75	1315	OQ288922	*Bacillus paramycoides*
DH13	97	98.96	1277	OQ288871	*Bacillus spizizenii*
AB7	97	98.78	1185	OQ288869	*Bacillus proteolyticus*
BC5	95	98.92	1260	OQ288870	*Bacillus paranthracis*

Bacillus species are known to form endospores, which means they are able to endure extreme conditions in their environment. *Acinetobacter*, *Clostridium*, *Bacillus*, *Pseudomonas*, *Desulfuromonas*, *Prevotella*, *Flavobacterium cytophaga*, *Staphylococcus* and *Streptococcus* were reported to be present at a municipal waste landfill site in Poland.

Bacillus species showed an ability for soil decontamination and possible use as an eco-friendly bio-fertilizer to increase crop productivity [61]. *Bacillus species* also produce various metabolites that range from hydrolytic enzymes to bio-pesticides and antibiotics [62]. This ability of *Bacillus* species to secrete extracellular proteins makes them desirable for use in food and drug production [63]. To the best of our knowledge, no studies have reported the presence of *Bacillus spizizenii* or *Neobacillus fumarioli* in landfill or their lignocellulolytic potential. However, other Bacillus strains have been reported to have cellulolytic abilities [26,32].

4. Conclusions

In the present study, we screened and isolated bacteria with enzymatic abilities from sediments. The seven most promising isolates were *Bacillus* species that were grown in both lignin and starch. The results showed that landfill bacteria, such as *Bacillus proteolyticus*, *Bacillus Sanguinis*, *Bacillus spizizenii*, *Bacillus paramycoides*, *Bacillus paranthracis and Neobacillus fumarioli*, were capable of multi-enzymatic activity, as confirmed by 16S rRNA sequencing. The screening of ligninolytic and hydrolytic bacteria may be a key to overcoming challenges in the adoption of lignocellulose as a raw material for bioprocesses. These

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

bacteria are capable of inducing responses from multiple lignocellulolytic enzymes, and further investigations are needed to determine how they can be adopted in bio-refinery.

Abstract

Due to environmental problems related to using fossil fuels and limitations in the sources of these types of fuels, renewable energies have sharply developed in recent decades. Renewable energy systems are applicable in various fields to provide clean energy. In the current study, medical and dental applications of renewable energies are reviewed. Based on the literature review, technologies based on renewable energy sources can be utilized in medical buildings and instruments. For instance, solar-based technologies can be applied in heating and cooling of hospitals and other healthcare facilities. In addition, the thermal energy of the sun is applicable in autoclaves and medical dryers. Although utilizing renewable energy systems for these applications requires more investment cost and probably more complicated structures, it would result in lower carbon dioxide emission which leads to sustainable development.

1 INTRODUCTION

Fossil fuels are the main source of energy for various technologies utilized for different applications [1, 2]. The main issues related to fossil fuels is the possibility of their depletion in near future and their unfavorable environmental impacts [3, 4]. Due to development in industrial activities and growth in world population, greenhouse gases emission have increased in recent years. Figure 1 shows the amount of world CO_2 emission between 1990 and 2016. In order to overcome these problems, renewable energy sources are appropriate alternatives for fossil fuels. In addition to developing renewable energies, enhancing the efficiency of energy systems by optimizing their working conditions, hybridization and waste heat recovery are other approaches to reduce greenhouse gas emissions [5–7]. The majority of the studies related to decreasing carbon dioxide emission of energy technologies, have focused on evolving renewable energies and optimizing the energy systems [8–10].

Renewable energies have been growing in recent decades due to their advantages such as lower greenhouse gases emissions compared with fossil fuels. Based on International Renewable Energy Agency report, by the end of 2017 the global capacity of renewable energy generation reached 2179 GW all over the world [12]. The trend of renewable energy capacity of the world in recent years is shown in Figure 2.

There are various renewable energy sources including solar, geothermal and wind [14–16]. These sources of energy can be applied to generate electricity or be used for other purposes such as heating systems and desalination units [17–19]. Photovoltaic (PV) modules directly convert the energy of solar irradiation into electricity [20]. Moreover, thermal energy of the sun can be applied to run thermal power plants and produce electricity indirectly. Integrating thermal power plants with solar energy will improve their efficiency and reduce greenhouse gas emission. In addition to electricity generation, solar energy can be used for other applications. Based on a study conducted by Compain [21], the thermal energy of

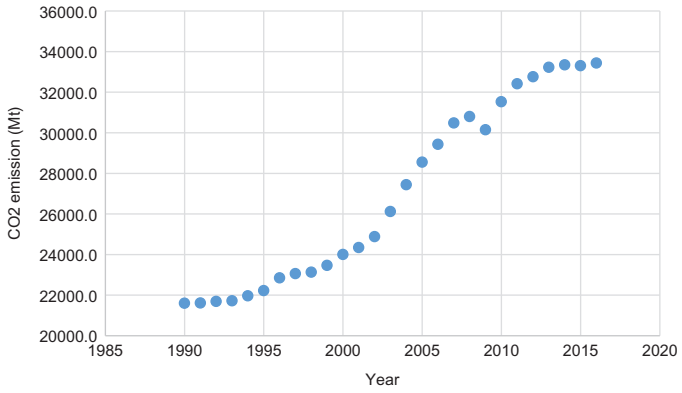

Figure 1. *CO_2 emission of the world [11].*

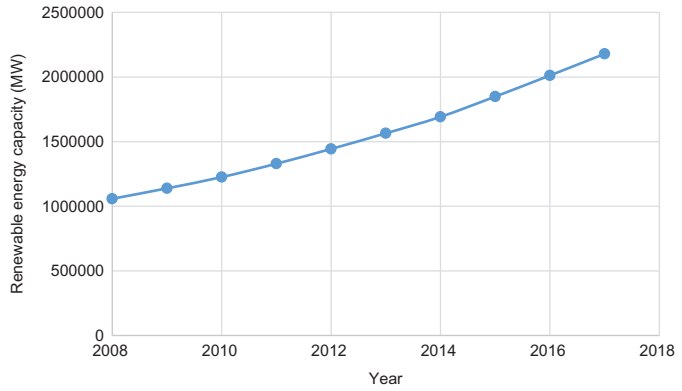

Figure 2. *World renewable energy capacity [13].*

various desalination systems can be provided by solar energy [21]. Other types of renewable energy source can be used for electricity generation both directly and indirectly. For instance, wind turbines are utilized to convert wind kinetic energy into electricity by using a generator. The heat extracted from geothermal sources can be used in power plants and heating purposes such as ground-source heat pumps [22]. Hydropower energy is another kind of renewable energy which convert energy of falling water into electricity.

Several industries and sectors use renewable energy technologies to become more environmentally-friendly [23, 24]. In the current study, various applications of renewable energy in medical and dental aspects are reviewed. A comprehensive literature review is performed and their key results are represented here.

2 RENEWABLE ENERGIES IN HOSPITAL AND CLINICS

Studies have shown that the share of hospitals in energy consumption of building sector is ~6% [25]. Hospitals and clinics have several facilities to provide required energy for heating, cooling and hot water preparation and etc [26, 27]. Figure 3 shows energy balance in hospital. Reduction in energy consumption of hospitals gained importance to achieve green hospitals [28]. Various solutions including regular maintenance of filters utilized in Heating, ventilation, and air conditioning (HVAC) systems, using isolating materials, applying aquifer systems and improving air conditioning systems are represented to reduce energy consumption in hospitals [25, 29, 30].

Proper energy management in healthcare centers can lead to energy saving up to 8.660 kWh/m^2 per year for buildings which are <5000 m^2 (without bed) [32]. This value decrease to 6.88 kWh/m^2 per year for the buildings larger than 5000 m^2 which have beds [32]. In addition to mentioned solutions, using appropriate technologies can significantly decrease energy and enhance the performance of air conditioning system [25, 33–37]. For instance, Renedo *et al.* [26] investigated various cogeneration systems working with gas turbine and diesel engine. It was observed that the size of systems and utilized control system have significant impact on the economic aspect. Since the electricity generation plays key role in the system economy, it was concluded that diesel engine is preferred. In another study [38], heat pipe heat exchanger was utilized in air condition system of a hospital located in Malaysia. The schematic of the existing and proposed air conditioning systems are represented in Figures 4 and 5. It was concluded that using heat pipe heat exchanger resulted in enhancement in the performance of the air conditioning system. In addition, results indicated that applying these types of heat exchanger can lead to save a total energy of 455 MWh in the scale of the case study.

Renewable energy sources can be used in energy supply systems of healthcare centers to obtain cleaner and more appropriate systems in term of economy [39, 40]. In a study conducted by Tsoutsos *et al.* [41], utilizing solar absorption cooling technology in a Greek hospital was investigated. The most important aim of the study was designing a zero-emission system in order to decrease both cost and carbon dioxide emission. In the first step of the study, meteorological data were collected which contained solar irradiation, wind speed, relative humidity, etc. Afterwards, the highest, mean and lowest required cooling and heating load of the building were obtained to design the technical specifications of the system. Subsequently, the solar cooling technology was selected, which was solar air conditioning (SAC), depending on building parameters including geometry, material utilized in construction, etc. Afterwards, the study focused on the sizing of the system. In the next step, a study was conducted on changing technical specifications in order to achieve optimal solution. Finally, the optimal solution was evaluated economically. Four scenarios were investigated in the study. Based on a scenario (which had solar fraction for cooling and heating equal to 74.23% and 70.78%, respectively), the utilized SAC system had 70 kW absorption chiller. In the conditions, the chiller was not able to provide needed cooling load, 50 kW compression chiller was applied in addition to the absorption chiller. It was concluded that the suggested system

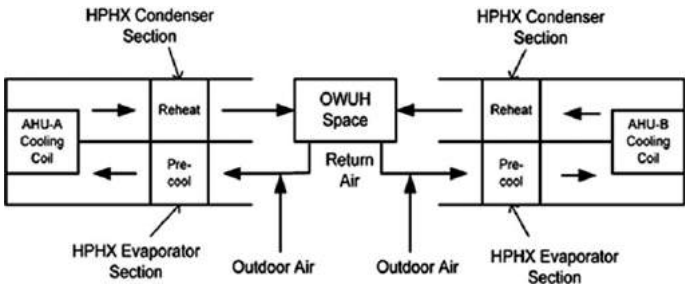

Figure 5. *Schematic of air conditioning system with heat pipe heat exchanger [38] (with permission from Elsevier).*

had environmental gain due to lower carbon dioxide emission. In addition, based on the performed economic analysis on this scenario, payback time was 11.5 years without funding subsidies; however, payback time can be reduced to 6.9 years by allocating the funding of 40% [41]. Utilizing ground-source heat pumps is another idea to reduce carbon dioxide emission in air conditioning systems [22]. In a study conducted by Vanhoudt *et al.* [42], an aquifer thermal energy storage with ground-source heat pump was applied for cooling and heating ventilation air of a Belgian hospital. The performance of this system was compared with reference facility which worked with gas-fired boilers. The flow of ground water and temperature were monitored in the proposed model. Results indicated that using the system which contained ground-source heat pump resulted in 71% lower energy consumption in comparison with the reference system. In addition, it was observed that carbon dioxide emission was reduced by 1280 ton over the investigated period (3 years). Based on economic analysis, the payback period for the proposed system was 8.4 years in the case of excluding the subsidies.

Isa *et al.* [43] performed a techno-economic evaluation of combined heat and power PV/fuel cell/battery energy system utilized in a hospital. The cogeneration system had grid-connected PV, battery, fuel cell, convertor, diesel generator and reformer. The diesel generator was utilized as back-up power module. The reformer was applied to generate hydrogen by reforming the hydrocarbons. Five configurations were investigated in the study. The configurations were stand-alone diesel generator, grid-connected PV system, grid-connected PV/battery, grid-connected PV/ fuel cell and grid-connected PV/ fuel cell/battery. Based on the analysis, the stand-alone diesel generator system produced the maximum carbon dioxide which was equal to 96 712 kg/year; while the grid-connected PV/fuel cell had the lowest emission equal to 20 402 kg/year. Based on economic analysis, the grid-connected PV/fuel cell and battery, had the minimum levelized cost of energy among the investigated systems [43]. A summary about the pollutant gas emission from the investigated configurations are represented in Table 1.

Sigarchian *et al.* [44] assessed a complex polygeneration system in a hospital and compared its performance with a reference system. The configurations of both systems are shown in Figure 6. The polygeneration systems utilized solar thermal energy, solar PV module and utility grid. Results indicated that using the polygeneration systems was able to reduce carbon dioxide emission and fuel consumption by 10–29% and 14–32%, respectively.

In addition to air condition systems, renewable energies are applicable for other purposes in healthcare centers. For instance, Bujak [45] carried out a study on heat consumption required for hot water in hospitals. The considered hospitals in the study were 715-bed university hospital which was located in Bydgoszcz and a 690-bed Provincial hospital. Results indicated that the mean annual consumed heat for the first and second mentioned hospitals were equal to 8.5 (Gj/year.bed) and 9.6 (Gj/year.bed), respectively. These required values for providing hot water shows that utilizing solar water heating systems can be a feasible idea based on economic and environmental criteria.

3 MEDICAL INSTRUMENTS

There are several medical instruments which requires electrical or thermal energy [46]. Autoclave is a pressure chamber contains fluid with high temperature and pressure [47]. Medical

Grid-connected PV/battery system	55 163				239	117
Grid-connected PV/FC system	20 402				88.5	43.3
Grid-connected PV/FC/battery system	25 708				111	54.5

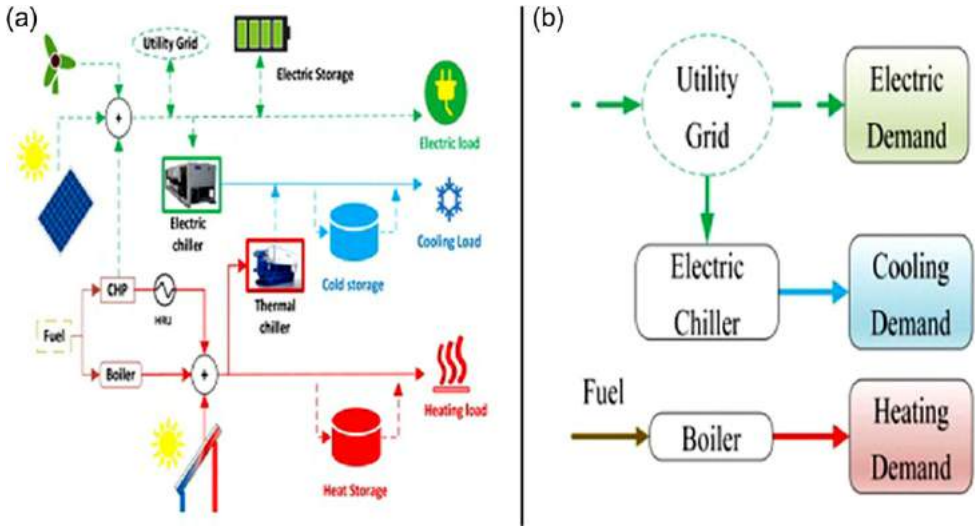

Figure 6. *Schematic of (**a**) polygeneration system and (**b**) reference system [44].*

Figure 7. *Photograph and schematic of a solar autoclave (I) unit of steam generator, (II) the connection section and (III) the utilized unit for sterilization. The parts of the autoclave are (a) sterilization vessel, (b) sensor of pressure, (c) temperature sensors, (d) relief valve, (e and f) control valves, (g) solar collector which has nanofluid heater solution, (h) check valve and (k) solar concentrator (a plastic Fresnel lens with 0.67-m^2 area of the surface) [50].*

autoclaves are utilized in order to sterilize equipment applied in surgery or dental treatment. In order to obtain fluid with high pressure and temperature inside the autoclave, it is necessary to use thermal energy. Solar energy can be applied to provide required thermal energy. Solar-powered medical autoclaves are appropriate choice for off-grid sterilization of medical and dental instruments [48]. Dravid *et al.* [49] conducted a study on solar autoclave. In the study, a concentrator which had concave

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

surface was used. The body of the autoclave was made of steel and the material of its surface was ionized aluminum sheets. A 40-L autoclave which had the similar working principles to pressure cooker was located in the middle of the metal ring. The needed heat was provided by the solar concentrator. Results indicated that using solar energy instead of LNG or electricity for heating the autoclave, led to 313.50 GBP annual saving [49]. Therefore, it can be concluded using solar energy for autoclave results in more cost-effective performance and lower greenhouse gases emission. In another study, Neumann *et al.* [50] investigated performance of a compact solar autoclave. In the designed autoclave, thermal energy of sun was applied for steam generation. The investigated solar autoclave is shown in Figure 7. As shown in Figure 7, concentrated solar radiation provide required thermal energy for steam generation. The produced steam enters the sterilization unit and after condensation returns to the solar collector. Utilizing nanofluid in this set-up resulted in more rapid increase in temperature of water and steam, which can be attributed to thermophysical properties of nanofluids [51–53]. By using this cycle during the sterilization process, it was possible to keep the temperature and pressure in the ranges of 115–140°C and 12–14 psig, respectively. These values indicate appropriate performance of the system.

In addition to solar autoclaves, thermal energy of the sun can be utilized for other purposes [54]. For instance, based on a study [55], hybrid solar collector technologies can be used in drying medicinal plants. By using solar irradiation and absorbing it by collectors, thermal energy for drying process can be provided. The main advantages of using these types of dryer is lower greenhouse gases emission and the possibility of using them as off-grid systems.

Medical implants which use electricity can enhance health of people [56]. There are some novel ideas such as electricity generation by utilizing solar cells which are subdermal [57]. The generated electricity by these cells can be used for bioelectronics mediums. Several factors can influence the generated power by applying these cells. Based on a study performed by Song *et al.* [57], the density of produce power was dependent on the thickness and tone of skin. It was concluded that brighter and thinner skin led to higher generated power density.

Renewable energy systems are applicable in the field of dentistry. A new type of toothbrush has been introduced which contains titanium oxide (TiO_2) N-type semiconductor. The basic principle working of these toothbrushes is decreasing in H^+ ions from the organic acids in plaque which results in its decomposition [58]. Solar energy can be applied in these types of toothbrush. For instance, in the study conducted by Rahman *et al.* [59], TiO_2 rod was inserted in the neck of the utilized brush. A copper wire connected the TiO_2 (which was positively charged) and the stainless steel rod in order to produce electricity. The energy source for electron generation was a solar panel. Results of the study revealed that using this type of toothbrush can have significant therapeutic effect on the prevention of dental caries.

4 CONCLUSION

In the present study, a comprehensive literature review is performed on the medical and dental applications of renewable energies. Based on the reviewed studies, renewable energy systems can be used in various tools and structures. For instance, by utilizing renewable energy systems, air conditioning technologies with higher efficiency and lower carbon dioxide emission is achievable for medical facilities such as hospitals and healthcare centers. Moreover, renewable sources can be applied to provide required heat for hot water and drying systems. In addition, there several medical mediums which can utilize renewable energies. Solar-powered toothbrush and solar autoclaves are among the most conventional devices. Moreover, some novel tools are applied to provide electricity for medical implants. These devices are subdermal and generate electricity by receiving solar radiation. The rate of electricity generation in these mediums depends on skin specifications such as its brightness and thickness.

The future studies should focus on the other applications of renewable energy systems in medical and dental aspects such as providing the required energy for dental turbines. Using appropriate renewable-based ventilations technologies and hybrid systems will lead to more environmentally-friendly and cost-effective systems. In addition, utilizing novel solar concentrator to provide required thermal energy of solar autoclaves, results in more reliable and efficient devices.

Optimal integration of battery energy-storage system with high penetration of renewable energy in radial distribution network

Hafsa Imra Sheikh*, Mahesh Kumar Rathi and Amir Mahmood Soomro

Department of Electrical Engineering, Mehran University of Engineering and Technology, Jamshoro, Pakistan

*Corresponding author. E-mail: hafsa.sheikh09@yahoo.com

Abstract

Considering the intermittent nature of renewable energy, a storage system to reserve power in off-peak hours and then to supply it during peak hours is necessary. However, if these storage devices in a network are not placed in an appropriate manner, the advantages can never be achieved. In this study, the allocation and sizing strategies of a battery energy-storage system (BESS) in an optimal way are proposed to improve the performance of the radial distribution networks. The test network adopted is a standard IEEE 33 bus network that is integrated with solar power. Simulations are carried out in DIgSILENT PowerFactory for the distribution network model and the process of optimization is done through MATLAB®. The optimization algorithm adopted is the genetic algorithm. The system is studied for 24 hours with a step size of 15 minutes, employing a time-sweep analysis of dynamic load. It is studied under three different scenarios and the results are compared. The results illustrate a considerable reduction in power losses in the case of the optimized BESS. The total losses before the optimization process are 16 365.57 kW. The total losses after the employment of the proposed solution are 10 246.5 kW, which means that the losses are reduced by ≤62%.

Introduction

These days, great interest has been aroused in reliable and flexible energy integration. It is a great challenge to balance power generation and consumption considering the stochastic nature of renewable energy [1]. Renewable energy is considered a path towards a clean and less polluted environment. It is seen as a possibility to reduce CO_2 emissions. The degrees of atmospheric pollution along with the sources of air pollutants have increased essentially over the years [2, 3]. At the same time, numerous research studies have been done on solar energy integration to meet the renewable-energy target [4]. Different policies for renewable energy-generation strategies have also been launched by some governments [5]. Furthermore, it is expected that by the end of 2025, the levelized cost of electricity of solar energy could fall by 43% [6]. Few research studies have also been carried out for loss minimization; however, a renewable energy source was not considered in the network [7]. Despite the environmental and sustainability benefits of renewable energy, one of the most important problems is the management of power. Mainly, the photovoltaic (PV) system generates power depending on the local insolation level according to that area and the time of day. Especially in local electricity grids, in which the percentage of generation from solar is higher than that from other conventional generating technologies, the management of power becomes a challenge. The behaviour of the grid is disturbed due to these non-manageable energy-generating technologies. If the percentage of generated power through PV is low, the disequilibrium between production and consumption is not very problematic but if this percentage increases, the variability of electricity produced and its consumption become considerable matters. This intermittent power becomes the reason for the destabilization of power.

Therefore, the management of electricity produced by such intermittent sources is under great consideration these days [8, 9]. One of the possible solutions suggested by the literature is to use hybrid renewable-energy systems for this issue of intermittency, to integrate different renewable-energy resources in an optimal manner [10]. In this system, sources with lower generation during a period can be compensated for by sources having a higher generation level during that period [11]. Thus, system efficiency and supply reliability can be increased [12]. The optimal sizing of generation units is reviewed in detail in [13] and different control strategies for renewable energy in [14].

The other solution suggested by the literature is the battery energy-storage system (BESS) [15]. The energy-storage system (ESS) is the key technology for the reliable integration of renewable energy resources [16]. The surplus amount of energy is stored in the ESS, which is fed when consumption is higher than generation. If the ESSs are not placed in the correct manner in a distribution network, the benefits from the ESS cannot be achieved [17]. As a result, optimal sizing and allocation of the BESS have become crucial areas of research. However, in this study, the allocation and sizing strategies of the BESS in an optimal way are proposed to improve the performance of the radial distribution networks.

The problem of the optimal sizing and siting of the BESS in the distribution network has been significantly studied in the literature [18]. In [19], the authors used a modified non-sorting dominated genetic algorithm (GA) for the location and size of distributed generation (DG) optimally in distribution networks (DNs). The objective function is power-loss minimization, which improves the voltage profile of the system. This proposed methodology was tested on an IEEE 33-bus system. Misplacement or misuse of energy-storage devices can lead to several network performance issues in terms of voltage and frequency regulation, power quality, reliability and load controllability [18]. To achieve the optimal operation of an ESS, an appropriate way of placement is required for improvement in voltage and power quality [19, 20], peak-demand reduction [19], relaxation in distribution congestion [18], power-flow control [18], power-loss minimization [21], network security and cost reduction [8, 9], RES integration [10] and system effectiveness.

There are several variables that are defined to approach the optimal sizing and siting of a BESS in a distribution network, such as optimizing technique, performance metrics for optimum evaluation, battery technology, and modelling and testing of the network.

After a successful analysis of resources and estimation of solar production, a system needs to be developed to maintain the balance between generation and consumption patterns [16]. Intermittent PV production throughout the day can be smoothed by including ESSs and filling in the gaps. The smooth production of renewable energy throughout the day can be achieved through ESSs. They have the ability to handle ramps or the frequently known duck curve [7]. The ability to handle the load ramp cannot be done through traditional conventional generators but it can be handled very quickly through energy-storage devices [22]. The BESS has attracted considerable attention from researchers because of its advantages such as speedy response, controllability, energy management and reliability improvement [5]. Therefore, locating grid-scale ESSs becomes important in improving distribution network performance and minimizing the issues. If not placed in the correct manner in a distribution network, the benefits from the ESSs cannot be achieved [23]. However, in this section, an extensive review of the literature on optimal allocation and sizing of batteries is presented. The term 'optimization' means to reach the established goals with the help of available resources through a set of processes. The general optimization process algorithm for optimal sizing and placement has the following steps:

(i) Identify the problem to be analysed in a network and the support solution provided by the ESS or we can identify the major objective, such as peak shaving, loss minimization, power quality and reliability, etc.
(ii) Formulation of the fitness function and necessary constraints related to the optimal sizing and placement of the BESS.
(iii) Evaluate the fitness function using optimization techniques such as analytical or meta-heuristic approaches.
(iv) Update the fitness value and current best location and size of the BESS.

The general flow chart of the heuristic optimization approach and the utilization of GA in the optimal allocation are shown in Fig. 1.

The objective of this research is to reduce the power losses in a radial distribution network given the constraints on power balance, bus voltage, energy-storage power, charge/discharge balance and remaining capacity of the ESS. The optimal placement and size of the ESS are determined by the GA optimization method. Several GA approaches have been utilized in other studies [15, 17]. These studies highlight the effectiveness of GA compared to other stochastic methods based on the processing duration and error percentage of the solution. In this study, DN

data and BESS data were fed as inputs into the GA. The algorithm processes these data through many iterations and the resultant is the optimal place for a BESS that assures the minimum power loss in the distribution network.

DIgSILENT PowerFactory (DPF) provides solutions for distribution network problems such as system design, modelling and optimization capabilities, grid interaction skills in a multi-user environment and data handling [24]. MATLAB® is used to control the system models developed in DPF and to facilitate genetic optimization. Furthermore, electricity production from renewable sources such as solar energy varies with changing solar radiation; thus, power generation is a function of time. Performing load-flow simulations during a certain time (in this case, a 24-hour period) in the different nodes of an electric power system requires the use of quasi-dynamic simulation, a time-varying load-flow calculation tool. Different researchers suggest that quasi-dynamic methods, as compared with quasi-static methods, not only improve the fidelity of the simulation of the process, but also reduce the processing time of the dynamic simulations. The main contributions of this paper are summarized as follows:

- An optimal BESS placement is carried out based on GA to significantly reduce the overall system power losses associated with the integration of high penetration levels of solar PVs. Although a similar investigation was carried out in [25], a unity power factor (p.f.) approach is applied on the ESS dispatch (i.e. the ESSs only inject P to the network). In this study, however, the ESSs inject both the P and Q to the network for better performance improvement with variable p.f. on the dispatch of an ESS.
- The effectiveness and robustness of the proposed methodology are comparatively tested and validated by different approaches on IEEE 33 bus systems. The first approach studied assumes that only the PV is contributing to the network and the voltage at the farthest node, such as bus no. 18. These values of voltages are later compared with the proposed network, such as after installing the BESS at the optimal place. The second approach is that active power losses are studied with and without the employment of the BESS of the overall DN. Overall, active power losses are reduced after the employment of the proposed strategy.

1 Methodology

1.1 Quasi-dynamic simulation

A quasi-dynamic simulation is offered by DPF for the execution of medium-term to long-term electrical studies. It performs several load-flow calculations with user-defined time-step size. This tool is useful for dealing with studies in which long-term generation and demand profiles are defined and network models are developed considering expansion stages and variations [26].

The main benefit of this type of simulation is that it provides faster calculation results because it does not require solving all the mathematical expressions. Other researchers [27, 28] have suggested that quasi-dynamic simulation language offers better accuracy than other methods such as quasi-static. Quasi-dynamic simulations have been used in electrical studies into

units such as circuit-interruption devices, PV energy systems, ESSs and distribution network studies. In this work, the 'Quasi Dynamic' tool (Fig. 2) is used to analyse the distribution network with varying demand in order to determine the behaviour and changes in system dynamics when some nodes in the system include solar DG.

By modifying the load, each node in the system has a different demand that varies moment by moment. This new behaviour is analysed under different scenarios. The load flow is calculated every minute for 24 hours in order to identify the changes in the network variables such as power losses and voltage profiles. In order to analyse the simulation results, the IEEE 33 bus system was used as a test system model (Fig. 3).

1.2 Load modelling

The proposed load model is the IEEE 33 bus test system. It is designed using DPF. The system consists of 33 buses and 32 nodes with a current-carrying capacity of 400 A from Node 1 to Node 9, whereas other lines have a capacity of 200 A. The base voltage is 12.66 kV and the base power is 10 MVA. The total active power load is 3715 kW and the reactive power load is 2300 KVAr. Since the base system is modelled with a firm power load, it is required to simulate the load variations over time to study the dynamic nature of load under a 24-hour period. The quasi-dynamic simulation is used to calculate the set of time-dependent load-flow calculations. The standard Bundesverband der Energie- und Wasserwirtschaft load profile is utilized [30]. The basic system parameters are shown in Table 1.

1.3 Solar PV modelling

There are a few factors that affect the generation from PV models, such as rated power, solar irradiance and temperature. The PV system generates power during the day. The output power of the solar module is shown in Fig. 4. It is generated based on Karachi city solar irradiance measured on the hottest day of the year, which is 21 July. The maximum output power is ~2.2 MW at 1 p.m. The number of parallel inverters is 20 000. The watt/panel is 110 watt so 110 × 20 000 = 2.2 MW. Integration of PV systems in DPF requires basic data for the network model. The type of PV panels is Aleo 150-L. The basic data for the PV model are shown in Table 2.

1.4 BESS modelling

The ESS is simulated using the built-in static generator unit that is used to model any non-rotating power-generation and storage unit that is connected to the AC grid through an inverter. The use of this element is an appropriate approximation and it is also supported by DPF in which ESSs are represented by static generators.

To implement this time-varying system, the time-dependent load-flow script 'time sweep' is utilized. The objectives achieved by this framework are: appropriate objects on the grid topology such as PV units, energy-storage units and time-dependent loads are identified; specific system parameters are then read to perform the time-dependent load-flow analysis later to extract the results; the adopted load-flow script analyzes the name of storage units and its capacity to calculate the state of charge with user-defined time-step sizes.

In this research, it is assumed that the BESS is fully charged at the start of the day and discharges gradually as time goes by[31]. In order to simulate a battery storage unit over a period of time, the unit is modelled considering the following three parameters:

(i) maximal charge and discharge power;
(ii) charge–discharge efficiency;
(iii) storage capacity.

The battery storage unit is used for the modelling of a BESS. The active power rating of the battery is 1.1 MW.

1.5 Optimization method

GAs are optimization techniques used to solve non-linear or non-differentiable optimization problems. GA uses concepts from evolutionary biology to search for a global minimum. The name 'genetic algorithm' comes from the fact that the algorithm is mimicking evolutionary biology techniques. GA works by starting with an initial generation of candidate solutions that are tested against the objective function, then generating subsequent generations of points from the first generation through processes such as selection crossover and mutation.

The GA runs its iterations until it converges to the best objective function, i.e. when the fitness function value is no longer changing or it is changing by a really small amount.

This paper employs GA as an optimization method to optimally size and site the BESS in a distribution network. This process is done using MATLAB® programming. The system summary from DPF is synchronized with MATLAB® for the process of optimization. It is assumed that the PV system only supplies active power and is placed arbitrarily at buses. The objective function is to reduce line losses, formulated as:

$$Ploss = min \sum_{t=1}^{Ttotal} \sum_{i,j=1\ i\neq j}^{nbr} g\ i,j(U_i^2 + U_j^2 - 2U_iU_jcoscos\ (\theta_i - \theta_j)) \quad (1)$$

where Δt represents the time interval; t_{total} represents the total time period considered, gi,j represents the conductance between

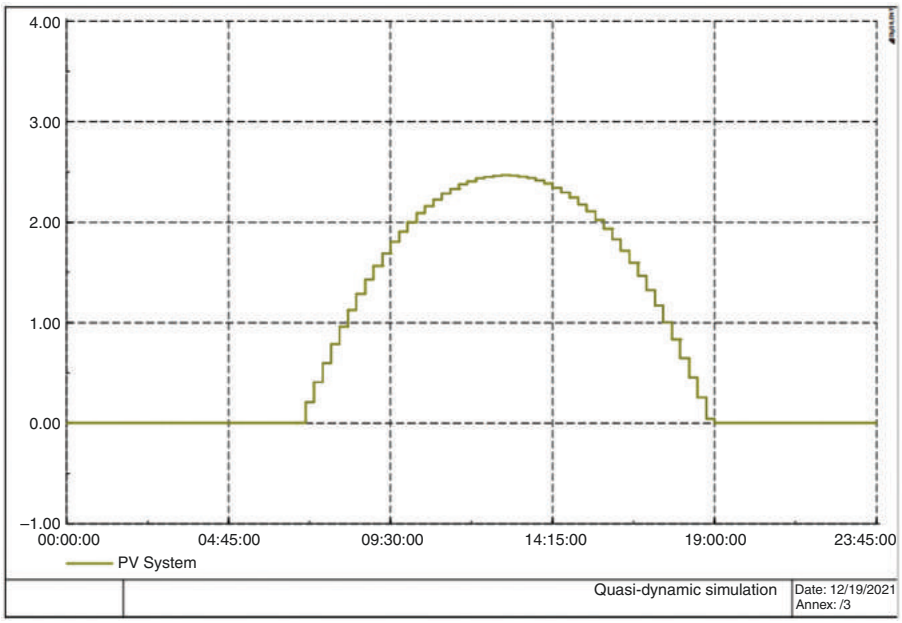

Fig. 4: PV output curve.

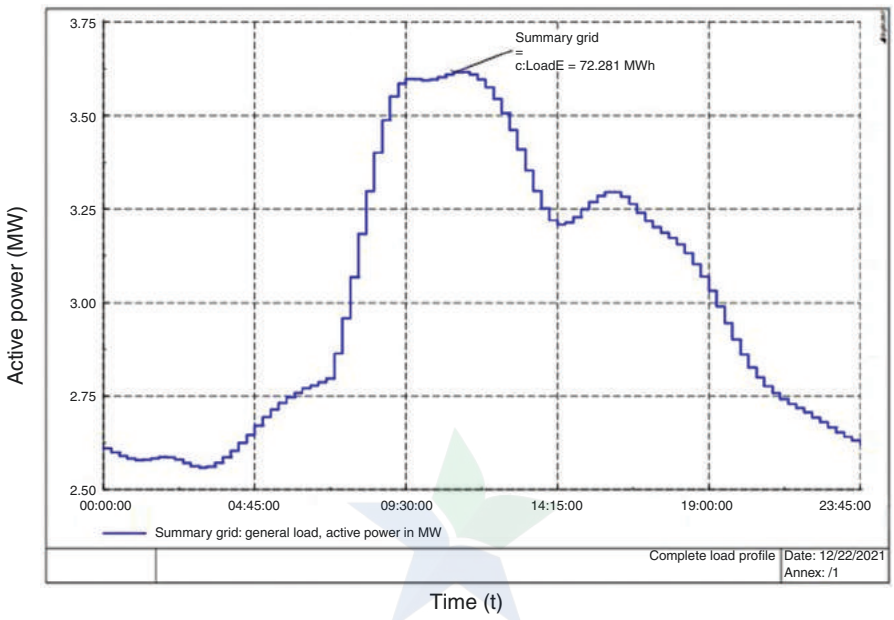

Fig. 5: Load profile of 1 day.

PERPUSTAKAAN NASIONAL

buses *i* and *j*, *nbr* represents the total number of branches in the network, U_i and U_j represent the voltage magnitudes of the buses *i* and *j*, and θ_i and θ_j represent the voltage angles of buses *i* and *j*.

Equation (1) interprets the expression for total network power losses based on the AC power-flow equation. For each and every evaluation of fitness function, the non-linear AC power flow is calculated. In addition to the above objective function, the optimal network configuration has to satisfy the following operational constraints:

$$U_i^{min} \leq U_i \leq U_i^{max} \quad (2)$$

$$S_b \leq S_b^{max} \quad (3)$$

where U_i^{min} represents the minimum voltage magnitude for *i* buses, U_i^{max} represents the maximum voltage magnitude for *i* buses, S_b represents the actual power flow and S_b^{max} represents the maximum actual power flow. U_i^{min} and U_i^{max} represent the voltage limit of each bus and S_b^{max} represents the maximum current level of each branch b in terms of actual power flow.

The whole search process of the proposed method for determining the location and size of the BESS to minimize total active power loss is described in detail as follows:

Step 1: Define the input data (V_{rated}, R_L, X_L, PV and MVA_{base}) to simulate the studied distribution network in DPF and evaluate candidate buses to find the best location for the BESS installation.

Step 2: Initialize the parameters of the algorithm.

Step 3: Select one candidate bus as the location for the BESS installation.

Step 4: Execute the algorithm (as in Fig. 1) to solve the optimization problem.

Step 5: Conduct a load-flow process at the current candidate bus at which the BESS is installed.

Step 6: Evaluate the objective function at that point.

Step 7: Update the best solution.

Step 8: If the maximum iteration is reached, calculate optimal coefficients (Step 9); otherwise, continue optimization (Step 4).

Step 9: Obtain optimal coefficients at the current candidate bus at which the BESS is installed from Step 3.

Step 10: If the candidate bus is the last candidate, proceed to the optimal BESS installation (Step 11); otherwise, select the next candidate bus and execute the algorithm (Step 3).

Step 11: Determine the optimal siting of the BESS installation, which is the candidate bus providing the minimum value of the objective function, such as reduced power losses.

Step 12: Substitute the obtained coefficients in the BESS unit.

2 Results and discussion

The results were obtained using DPF for model simulation and MATLAB® for the optimization process. The standard IEEE 33 bus system is taken as the base case and its data are shown in Table 2. The data are modified to create a dynamic load demand and system dynamics are studied for 24 hours with a time-step size of 15 minutes (Fig. 5). There are three cases in this study. The system load is dynamic in all three cases, which is 72.28 MWh. The load is maximum at around 9.30 to 11.30 a.m., as shown in Fig. 5. The first case is the base case that includes no PV and BESS. The total losses in that case were 16 365.57 kW. Fig. 6 shows the total active power losses in a complete day of 32 branches.

The total losses after the employment of the proposed solution are 10 246.5 kW, which means that the losses are reduced by ≤62%. The reduction in total active power losses in each case are shown in Figs 7 and 8.

The voltage profile of each bus in the base case is shown in Fig. 9. As the voltage reduces at a node with respect to an increase in the distance from the supply side, only the farthest node is studied in this research, which is bus no. 18. The voltage at bus no. 18 in each case is shown in Fig. 9. It is evident that the voltage has improved after the employment of the proposed solution. The voltage between the midnight hours has improved by 0.02 p.u. Hence the overall system voltage has been improved by 97% and it is under the stability limits.

3 Conclusion

In this research, a GA approach was utilized to find the optimal size and placement of a BESS integrated with PV and a grid in the IEEE 33 bus system. The overall system active power losses are reduced and the voltage is improved after the employment of the proposed solution. Several cases have been established to verify the results compared to the test system. The simulation results reveal that the overall system losses under dynamic load without the usage of BESSs are 16 365.57 kW and after the placement of distributed BESSs they are reduced to 10 246.5 kW. Therefore, losses in the proposed solution are reduced by 62%. The improvement in voltage is also justified in the results by the use of BESSs. Intermittent renewable-energy systems, especially at higher levels of penetration, can also be made stable by this application of BESSs. For future work, the proposed solution can be tested for other renewable-energy integrations as well, such as wind, fuel-cell, etc. The objective function can be expanded as a multi-objective optimization approach and this study will contribute to the efforts.

Portfolio optimization of power plants by using renewable energy in Iran

Seyedeh Asra Ahmadi[1], Seyed Mojtaba Mirlohi[1], Mohammad Hossein Ahmadi[2,*] and Majid Ameri[1]

[1]*Faculty of Industrial Engineering and Management, Shahrood University of Technology, P.O. Box 3619995161, Shahrood, Semnan Province, Iran* [2]*Faculty of Mechanical Engineering, Shahrood University of Technology, P.O. Box 3619995161, Shahrood, Iran*

Abstract

Lack of investment in the electricity sector has created a huge bottleneck in the continuous flow of energy in the market, and this will create many problems for the sustainable growth and development of modern society. The main reason for this lack of investment is the investment risk in the electricity sector. One way to reduce portfolio risk is to diversify it. This study applies the concept of portfolio optimization to demonstrate the potential for greater use of renewable energy, which reduces the risk of investing in the electricity sector. Besides, it shows that investing in renewable energies can offset the risk associated with the total input costs. These costs stem from the volatility of associated prices, including fossil fuel, capital costs, maintenance, operation and environmental costs. This case study shows that Iran can theoretically supply ∼33% of its electricity demand from renewable energy sources compared to its current 15% share. This case study confirms this finding and predicts that Iran, while reducing the risk of investing in electricity supply, can achieve a renewable energy supply of ∼9% with an average increase in supply costs. Sensitivity analysis further shows that with a 10% change in input cost factors, the percentage of renewable energy supply is only partially affected, but basket costs change according to the scenario of 5–32%. Finally, suggestions are made that minimize risk rather than cost, which will bring about an increase in renewable energy supply.

1. INTRODUCTION

The prosperity of modern society depends on the stability of its energy supply. Unfortunately, nowadays, most countries are facing more challenges day by day like sustainability, chiefly in the electricity area. The shortage of investiture in this area leads to instability in the continuous electricity supply, which will reduce the growth and development of countries' welfare [1]. The main reason for the lack of investment is the investment risk in the electricity sector. In the fossil fuel power generation method, energy production is based on low-cost technologies in which the devices are advancing slowly in comparison to the current rapid growth in other industries. Also, energy technologies are homogeneous, and energy prices are stable. However, today's energy planners are faced with extremely complex environments full of uncertainty and risk. With the decline in fossil fuel reserves worldwide and environmental concerns such as pollution and global warming, countries are increasingly using renewable energy in their energy supply portfolio. Environmental pollution and emission of hazardous gases to the atmosphere can cause acid rain and other environmental damages that may lead to global warming and other harsh climate problems. These negative impacts can be reduced by utilizing renewable energy sources. In addition, producing power from renewable energy resources in case of availability [2] can decrease the dependency of the country on fossil-based power technologies [3]. It is predicted that renewable energy will be the main supplier source for the required demand in the future of clean power production [4]. The advantage of renewable energy resources is that they are close to the final consumers that make them economic due to decrease in transmission costs [5]. These resources show an ability to meet the energy demand at an appropriate and fixed level in a progressive manner. It should be high-

lighted that the dependency on a single energy carrier increases the energy production risk. Therefore, it is necessary to diversify energy production resources so as to achieve a sustainable energy portfolio [6]. In addition, the associated return of investing in the renewable power sector makes it invaluable for investors. It has been shown that investing 440 000$ for installing four wind turbines with a grid in which 84% of its demand is supplied with renewable energy can bring back the investment in 4 years [7].

2. INTRODUCTION TO IRAN

Iran is a country located in the Middle East with a population of 83 million in 2020 [8] and is considered a developing country (Figure 1). Iran is one of the richest countries of oil and natural gas in the world. This has affected the energy system in Iran. Oil and gas have allocated 44.5 and 54.5 of the total energy share, respectively, 90% of the electricity and 80% of Iran's export share [9]. As mentioned before Iran is the second Middle Eastern country that benefits from various energy resources. In addition to abundant conventional sources of energy, like oil and natural gas, the country can exploit from large renewable energy resources such as solar, wind, biomass, geothermal, hydro, etc. Moreover, oil reserves are limited and the next generation share of these resources must be considered so that they can utilize these badly treated treasures better. Iran will face a huge increase in electricity demand in future years as a developing country. Figure 2 shows electricity consumption in Iran. Extreme subsidies for energy production from fossilized resources such as oil and gas are because Iran is a petroleum-producing country. This is one of the most important causes that renewable energies in Iran have not developed. Iran is among the 20 countries that have a share in the 75% spread of greenhouse gases due to the expansive consumption of fossil resources in providing the necessary energy. Unfortunately, Iran the OPEC's second largest producer and exporter country experienced a significant rise in energy consumption and pollutant emission in recent years among developing countries. Iran has a high per capita energy consumption compared to other developing countries. Iran has a huge amount of CO_2 emission, which has placed the country among the top 10 emitting countries [10]. Global climate change has become a potential threat, and fossil fuel consumption has had the highest contribution to greenhouse gas emissions. In 2020 the fossil fuels releasing carbon dioxide (CO_2) emission were about tones in Iran (Table 1). Air pollution means a combination of air with gases to lead to a decrease in the quality of the air. Pollutant elements are carbon dioxide, monoxide, sulfur dioxide, etc.

Year	CO_2 emissions	Mt of CO_2
1990	171	Units
1995	245	Mt of CO_2
2000	312	Mt of CO_2
2005	418	Mt of CO_2
2010	499	Mt of CO_2
2015	553	Mt of CO_2
2017	567	Mt of CO_2

2.1. Iranian electricity market

Overall, electricity can be supplied from renewable and non-renewable energy resources. Renewable energy resources are considered to be a proper solution to sustainable targets in economic, environmental and social perspectives. Renewable sources of energy such as solar, biomass, wind, tidal, etc. are considered as the fuel source. However, these resources have several significant features. For example, the energy demand of remote communities can be supplied cost-effectively through renewable energy sources without imposing added investment, which is common when the demand is provided from fossil-based resources. From 25 years ago, the electricity access of residents in the developing countries has reached up to 1.3 billion, while the population growth is quite larger, i.e. 2 billion. Therefore, there are 700 million people in the studied period that cannot benefit from accessing electricity. Several affecting parameters such as cost, remoteness and demo-

PERPUSTAKAAN NASIONAL REPUBLIK INDONESIA

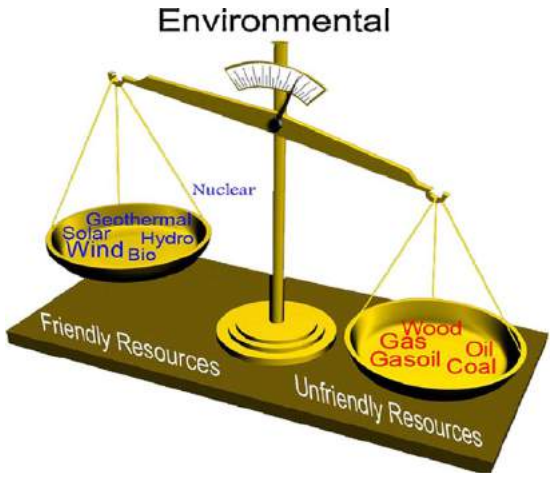

Figure 4. *Energy generation balance [13].*

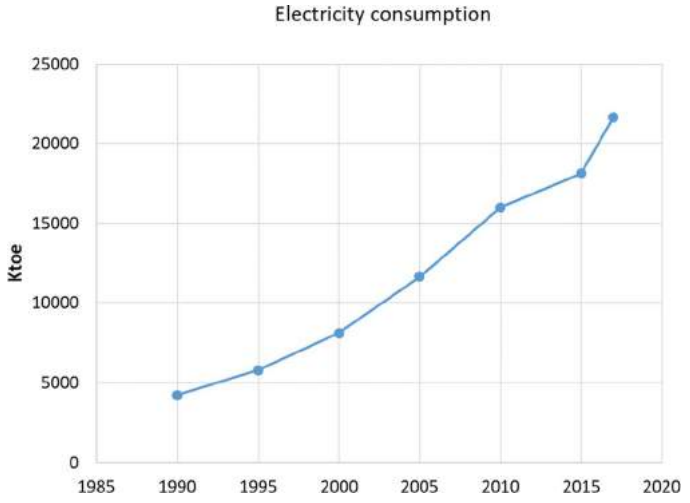

Figure 5. *Electricity generation by renewable and non-renewable sources [10].*

graphics make it difficult for the grid to provide electricity for these regions and those inhabitants. Hence, the remote area power system is a solution to supply electricity for these people [11]. As can be seen in Figure 3, in 2017, the largest amount of carbon dioxide produced belongs to the power and heat generation sector. The conventional energy systems are ecologically problematic and must be replaced by clean alternative energy systems. The life of fossil fuels is limited and the policy to burn them for their heat should be replaced by programs to save/utilize them towards achieving a sustainable development [12].

Although fossil fuel reserves are finite and the usage of fossil fuel sources has negative environmental effects. Renewable energy sources have gained significant importance due to their inexhaustibility, sustainability, ecological awareness and energy security supply. Thus. Renewable energy sources are believed to play an essential role, especially in the generation balance of electrical energy (Figure 4) [13].

Now, electrical energy is the major energy carrier that is utilized mostly in industries and in services. Hence, power consumption is one of the main factors in the development of societies. It is predicted that the total power consumption would be 33 000 TWh in 2035, which is two times more than that of 2008 [14]. This implies that electricity production capacity should be increased to respond to this growing demand. Therefore, installing new power plants is vital for this target since these resources are environmentally benign, adoptive, unlimited and also a proper choice for distributed power production. As time passed, people are becoming more and more aware of the hazardous effect of fossil fuels and the benefits of renewable resources; therefore, it is predicted that the portion of renewable resources will be increased in the future's energy portfolio. This statement is undeniable in the whole world, even for the countries in the Middle East that produce oil and it means that these countries will supply their electricity demand up to 16% from renewable energy resources in 2016, which is 16 times more than that of 2008 [14]. For all the reasons mentioned, it is necessary to add renewable energy along with fossil fuels in the energy supply portfolio for achieving sustainable economic growth in countries. However, it should be noted that the terms of sustainability are not defined sustainable for a long term period and it is changing at different times. Therefore, using an alternative source of power production with greater sustainability values would be an advantage to reach long-term sustainability.

Challenges of the country's energy sector, such as high-energy intensity, low-energy efficiency and productivity, high loss in various sectors of production, conversion and supply of energy, application of old technologies and high-intensity energy and high greenhouse gas emission rate, make it necessary to pay much more attention to renewable energy in the country. Adding these energy resources to the electricity basket will lead to diversity in energy resources, sustainable development and lead to energy stability in the country. In 2016, of the total 7 676 483.9 MW of power plant capacity, 11 836.2 MW and 256.4 MW were generated by renewable power plants, including and excluding hydroelectric power plants, respectively. Regarding the importance of renewable energies, the legislator in article 50 of the Islamic Republic of

Iran's Sixth Five Year Economic, Social and Cultural Development Plan Act obliges the government to maximize the share of renewable and clean power plants with the priority of non-governmental (internal and external) investment. The maximum use of internal capacity should be considered to reach at least 5% of the country's electricity capacity by the end of the implementation of the plan act. In 2016, the required power of the country is provided by governmental and private power plants, including 20 steam power plants, 53 turbine gas power plants, 25 distributed power plants, 21 combined cycle power plants, 46 diesel power plants, 56 hydroelectric power plants (large, medium, small, mini), 239 wind turbines, 17 PV solar farms, 5 biogas-fired power plants and 2 thermal recycling power plants. Of these, 6 steam power plants, 28 turbine gas power plants, 25 distributed power plants, 17 combined cycle power plants, 4 hydroelectric power plants, 228 wind turbines, 11 PV-solar farms, 5 biogas power plants and 2 thermal recycling power plants are owned by the private sector. Table 2 shows the portion of each technology in the portfolio of power generation technologies in Iran in 2016.

Table 3 also shows the consumption of fossil fuels in power plants in Iran in 2016. Due to recent policies to make more use of natural gas in power plants, widespread efforts have been made to deliver gas pipelines to power plants, since this fuel in comparison to others reduces the environmental impacts have an advantage of simple operation and also reduce the maintenance and operations costs [15].

As described in the preceding sections, four important sources of risk for investors in the electricity sector include investment and fuel costs, also operating, environmental and maintenance costs. According to Iranian legislation, fossil-based power plants have to pay 1% of their sales as a penalty for tax. Therefore, the environmental cost is assumed to be equal to that amount. The average of these four types of costs over the past 18 years is shown in Figure 6, Figure 7 and Figure 8 [15].

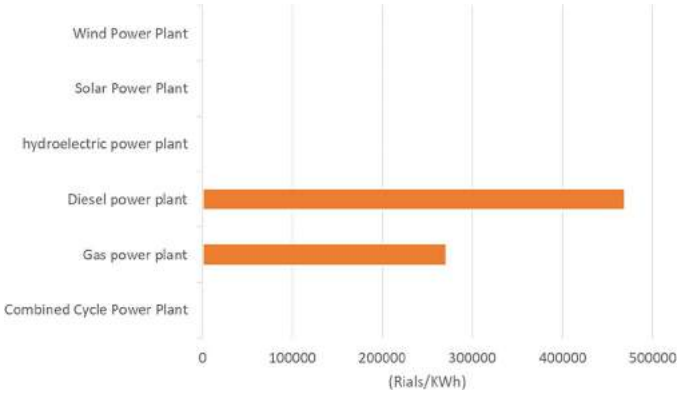

Figure 6. *Comparison of fuel cost through each technology [16].*

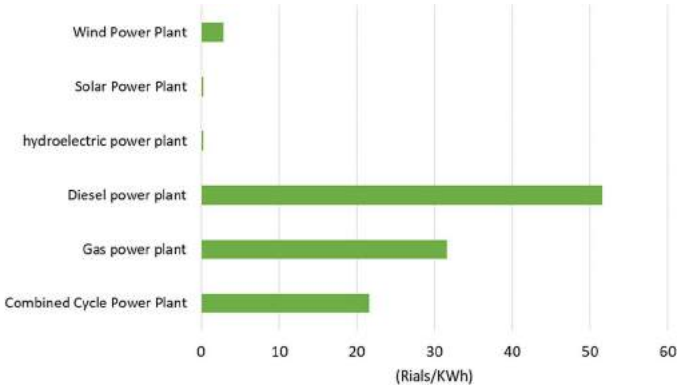

Figure 7. *Comparison of operation and maintenance through each technology [16].*

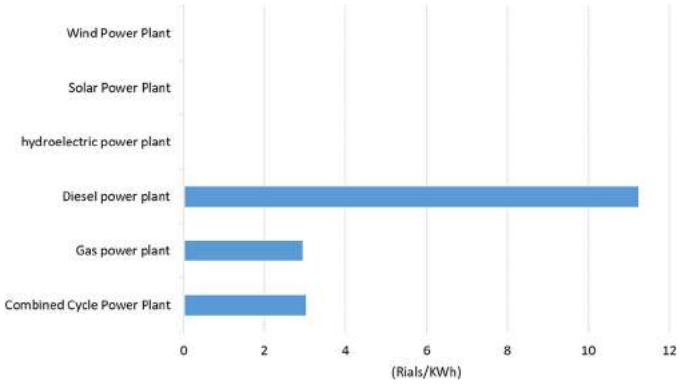

Figure 8. *Comparison of environmental taxes through each technology [16].*

3. STATEMENT OF THE PROBLEM

The main goal of this research is to optimize the existing risk in the power generation sector. One of the ways that are used to reduce the risk is known as diversifying the energy portfolio. According to Markowitz, portfolio diversification will reduce portfolio risk. This paper seeks to test the risk reduction effects of diversification in Iran's electricity portfolio. Therefore, introducing renewable energies and using these technologies alongside the existing tech-

PERPUSTAKAAN NASIONAL REPUBLIK INDONESIA

nologies, such as fossil fuel power plants, sound to be a viable solution. The rationale behind the diversification of stocks is that the overall risk of holding a large number of shares is far less than the risk of holding a small number [16]. The effects of diversification and portfolio formation on risk reduction have been extensively studied by financial experts [17], but it should be noted that portfolio management is not about the number of shares held, but its importance depends on the nature and degree of portfolio compound risk [16]. Brealey made extensive research and demonstrated that a portfolio of 11 stocks, selected according to risk and diversification characteristics, has significantly less risk than a portfolio of 2000 stocks selected regardless of the risk criterion [4]. The establishment and optimization of the portfolio in financial markets reduce the unsystematic risk of investment and drastically increase the investment performance [16].

Risk aversion is an intrinsic property of investors, so in complex and risky environments such as the investment environment, how to create optimal risk-based portfolios and reasonable efficiency and outcome is crucial. This target of this research is to provide a reasonable answer to the following two questions:

- Will the expansion of the portfolio of power generation technologies by adding renewable-energy bring about an increase in efficiency and reduce risk?
- Is it reasonable to add renewable energy to the country's electricity portfolio?

Awerbuch and Berger [18] were the first to apply and to implement the portfolio average-variance approach to the portfolio of regulated electricity markets in the EU electricity portfolio. In contrast, Bar-Lev and Katz [19] used a more efficient portfolio model that displays the risks associated with production costs such as construction, operating, maintenance and fuel costs. Based on this model, the authors examined the impact of using different production technologies. The results showed that the addition of wind energy or renewable energy technologies to fossil-fuel technology improved the overall portfolio efficiency. Awerbuch [20] explored the ability to reduce fossil fuel price volatility through portfolio optimization. It has been shown that renewable energy technologies can reduce generating costs, even if they include relatively higher costs, regardless of their potential to increase energy stocks. This result may seem irrational at first sight, but it is completely in line with financial theories.

Risk reduction of the electricity market in Iran due to the concept of investment risk optimization is examined by this section. Solar energy has the potential to meet the world's future needs as a renewable resource. Due to specific geographical conditions, Iran has great potential for using hydro, wind and solar energy and these God-given blessings can best be exploited if new investments are made. This country is located in a region with about 300 sunny days, which is placed as the top countries in terms of solar irradiation. Hence, using solar and wind energy for a variety of reasons such as easy access and ease of conversion, adaptability to the environment life and their renewable feature is very desirable. If Iranian deserts will equip with radiant

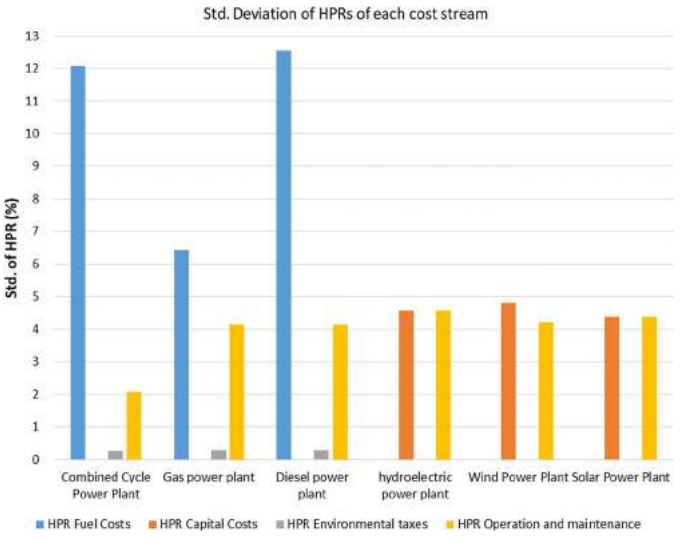

Figure 9. *HPR standard deviation of each production cost for different power plants (%).*

energy-receiving technologies, Iran has this potential to supply the energy needed for part of the Middle East region and also become an active country in exporting electricity. Fossil resource constraints, the high annual consumption of energy in Iran, the expulsion of Iran from oil exporter countries from the last century and the consequent disruption of oil exports make the country's development process severely affected if there is no planning to progress. Investing in the solar power industry is an investment in energy independence, and countries that can expand their solar infrastructure and electricity grid faster will be one step ahead of their opponents in competing for electricity generation and economic development.

Holding period return (HPR) is defined as an efficiency index of a portfolio as the percentage of changes in spending flows in 1 year in comparison to the previous year. The portfolio risk equals the standard deviation of the HPR of production costs. HPR is calculated as follows:

$$HPR = (EV - BV)/BV \tag{1}$$

In Eq. 1 EV equals the cost of the year 't + 1' and BV is equal to the cost of the year 't' [21]. For all cost streams, the value of HPR is calculated and is illustrated in Figure 9.

As shown in Figure 9, fossil fuel power plants have a cost, risk percentage of fuel cost risk, while renewable power plants do not. In other words, renewable power plants have a high investment cost.

Portfolio theory is commonly used in the context of financial securities in the estimation of the probable risk of stocks and returns perform based on annual volatility. In the case of the electricity production portfolio, costs are calculated as production costs (Rials per kWh) [18]. This analysis uses a similar concept of portfolio costs (technologies) and their returns and their share of

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

the portfolio's overall risk.

$$E\left(\sigma_p\right) = \sqrt{\left[\sum_{(i=1\ to\ n)} w_i^2\sigma_i^2 + \sum_{(j=1\ to\ n)} \left(w_i w_j \mathrm{cov}_{ij}\right)\right]} \quad (2)$$

3.1. Methodology: simulation and optimization for portfolio risk analysis

One of the methods that is used to calculate the portfolio risk and return period is the portfolio theory. In this study, a similar approach as Awerbuch and Berger [18] is used to calculate the costs of portfolio and return period to evaluate the overall portfolio risks. The schematic layout of this experiment is illustrated in Figure 10.

3.2. Mathematical formulation

The expected cost of the portfolio is defined as the average expected cost of production of the assets of each technology:

$$E\left(c_p\right) = \sum w_i \bullet E\left(c_i\right) \ \ where\ i = 1.2.\ldots.n \quad (3)$$

where w_i is the share of ith technology in the portfolio, and $E(c_i)$ denotes the expected average cost of production in the ith technology in Rials per kW.

Expected portfolio risk ($E(\sigma_p)$, where σ_p is the standard deviation of the portfolio) is estimated as annual changes in production costs. This is also a weighted average of the variance of the costs of any technology that is considered by their co-variance.

$$\mathrm{Minimize}\left(E\left(\sigma_p\right)\right) = \mathrm{Min}\ \sqrt{\left[\sum w_i^2\sigma_i^2 + \sum \left(w_i w_j \mathrm{cov}_{ij}\right)\right]} \quad (4)$$

where $i \neq j.i = 1.2.3.\ldots.n$ and $j = 1.2.3.\ldots.n$

subject to $\sum w_i = 1$ and $i = 1.2.3.\ldots.n$

$$w_i^{min} \leq w_i \leq w_i^{max}$$

$$\sum w_i^{RE} \geq 0/15$$

where σ_i and σ_j are the standard deviations of the HPR of the annual costs in the years of i and j, respectively, and ρ_{ij} is the correlation coefficient between them. Here the co-variance of the HPRs of the two different assets of i and j is defined as $\mathrm{cov}_{ij} = (\rho_{ij}\sigma_i\sigma_j)$. The value of HPR is calculated for each technology and cost flow. Cost flows are defined as fuel, operating and maintenance costs and so forth. The smaller the ρ_{ij} among portfolio assets, the greater the diversification that ultimately reduces the expected risk $E(\sigma_p)$. To be specific, increasing portfolio diversification by more technologies addition can reduce investment risk, which may be due to the lack of correlation between portfolio components. Also, it supports the notion that adding renewable energies to the portfolio of risk-free technologies of fuel costs and environmental costs can reduce the expected risk of electricity supply.

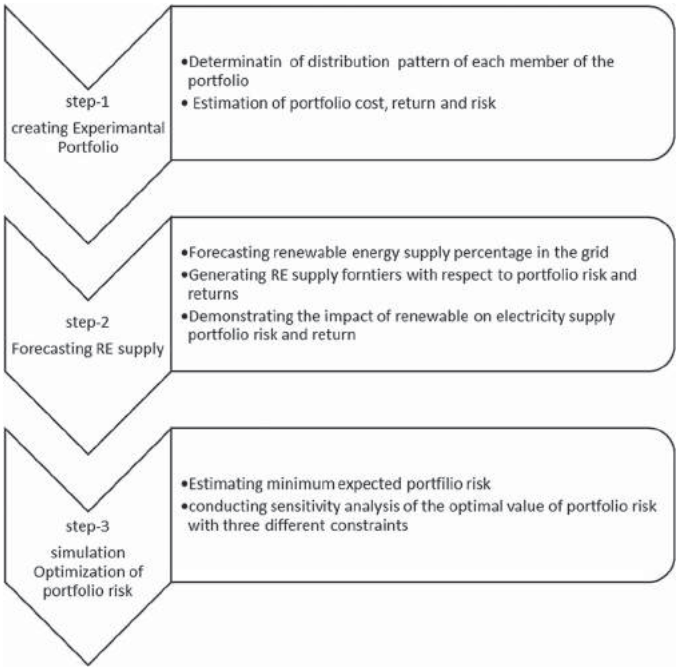

Figure 10. *Schematic illustration of the overall structure of the experiment [22].*

Table 4. *Properties of the current portfolio of power generation technologies.*

Technology	$E(c_i)$ Rials per kW	$E(\sigma_p)$ (%)	The portion of each technology (%)
Combined cycle	16833.9618	0.38	25.5
Steam	905239.2258	21.75	20.7
Turbine gas	7967434179	4.13	36.4
Diesel	26558507805	4.13	0.6
Hydroelectric	29693368.75	4.57	15.1
Wind	28181189	4.80	1.1
Solar	2942887.5	4.39	0.6

Minimizing the portfolio investment risk (E (p)) under given limitations of allocating various power production technologies in the portfolio in the target function of the model is used in this study. Considering the existence of n different power production technologies in the portfolio, the optimization procedure can be expressed as follows:

where, w_i, w_i^{min} and w_i^{max} represent the share of each technology, lower and higher limits of each technology in the portfolio, respectively. $\sum w_i^{RE}$ is the total capacity of renewable power production in the portfolio, which performs as a limiting factor in the optimization process. In the proposed model the need for renewable energy is compared with the basic scenario and it is predicted to be 15%, based on the available historical data in the energy balance reports and reported data from the Energy Ministry. The major objective of this limitation is to specify the optimal value of the power production capacity in Iran.

PERPUSTAKAAN NASIONAL REPUBLIK INDONESIA

Table 5. *Comparison cost, portfolio risk and cost with and without renewable technologies.*

	Risk of the portfolio	Expected portfolio cost (Rials per kWh)
Fossil-based technology without renewables	0.3924	727324766.5
Diversified portfolio (fossil technologies in addition to renewable technologies)	0.0174	65185381

3.3. Simulation

Based on the current structure of electricity production in Iran, Table 4, using the share of each technology from the existing portfolio to the total electricity mix that has existed since 2016, an experimental portfolio has been created. Each scenario is based on the cost of production by the weighted average cost of production in Rials per kWh and standard deviation of HPRs from the flow of input costs and expected return on investment of any technology that is calculated based on the reverse production costs are defined (Table 5).

Each fossil fuel technology is determined by a span of contributions and distribution patterns based on its historical share over the past 18 years in the experimental portfolio set. Finally, due to the historical data and using the standard statistical computing mechanism of Oracle Crystal Ball Simulation Software, the best distribution for each technology is estimated.

3.3.1. *Simulation optimization model*

In comparison to conventional optimization techniques, simulation optimization can deal with more scenarios. Besides, simulation methods have this potential to consider uncertainties in the inputs, which is the reason behind the utilization of this technique in this research. The simulation optimization can predict the target outputs while different sources of uncertainties and different parameters are applied, which may affect the performance of the optimization technique [23]. In order to obtain an invaluable output from a statistical manner, two discrete functions are happening in a logical manner based on metaheuristic search procedures that used the output response of the simulation model in parallel. This simulation, which is known as a system assessment stage, specifies the significance of inputs on the basis of pre-specified probability distributions and produces the most appropriate output for an optimizer module. The module then produces new inputs that are assessed by the simulation. This process is iterated for 10 000 times, with an exclusive arbitrary number each time, which is generated by the model and is progressively continued till it reaches to its global optima. Because of the presence of the uncertainties in the inputs and the degree of complicatedness in the output targets, it is difficult to obtain the solution space with normal optimization approaches and it is predicted that using conventional optimization techniques may lead to stop in the local optima instead of the global optima. This problem can be surmounted by applying adoptive memory and population sampling methods with the help of metaheuristic optimization techniques. Therefore, the Crystal Ball OptQuest is utilized, which benefits from the above-mentioned advantages.

3.3.2. *Simulation technique*

Spreadsheet calculation and simulation approaches are used in this proposed risk-analysis model, to evaluate the influence of different inputs on the targets and objectives of the system. Statistical distributions were employed to determine the different inputs of the problem. A model is simulated with the Monte Carlo method, which randomly and continuously produces values for uncertain values. The used probability distributions are arbitrary and independent. In this model, the random probability generated for one trial is completely dependent and does not have any effect on the next value. Crystal Ball applied the Monte Carlo model by employing spreadsheet values with explicit estimations, assumptions and targets in a three-phase procedure including producing an arbitrary number for each assumption pre-given probability distribution, recalculation of the spreadsheet and producing an estimated value in the designed model. This procedure is progressively continued until it comes to its defined stopping point, here 1000 iterations. In order to avoid repeated numbers, a Multiplicative Congruential Generator ($[(r \leftarrow (62089911.\ r).\ \mathrm{mod}(2^{31} - 1)]$) is employed [22].

4. RESULT

At the first step of the examination, each technology in the experimental portfolio was designed to separate risk–return and risk–cost diagrams to illustrate the overall relative position of each technology in terms of risk, cost and return characteristics. Simulations were performed to predict the percentage share of renewable energy (within the experimental sample of electricity generation) under certain circumstances concerning generation costs and risk. Finally, simulation and optimization were performed to minimize portfolio risk.

4.1. Risk assessment of cost and return of the portfolio

As discussed earlier, HPR as the output and risk dependent on each technology is the standard deviation of the annual HPR changes of each input cost component. This shows how a mixture of technologies in a portfolio can treat in terms of risk reduction and efficiency. Using equations (3) and (4) the return and risk for each technology based on the return maintenance behavior of the diverse input costs are estimated (Figure 11, Figure 12).

4.2. Forecast of renewable energy supply

Simulations have three purposes. The first objective is to predict the amount of renewable energy supply in Iran without any tech-

nical, financial or environmental constraints. The second goal is to create two distinct boundaries for renewable energy supply, which relate to the expected risk and return, respectively. Finally, it aims to show the impact of renewable energy on the technology portfolio of electricity in terms of risk and expected costs in Iran.

As can be seen in Table 6, with the assumptions of the presented distribution functions of input technologies in the simulation procedure of the power plant, a simulation model is predicted to supply up to 10–15% of whole electricity in Iran over the next decade; until 2028, it leaves all other conditions to control these energies. We use a simple prediction method that optimizes the prediction parameter to lower the error between historical data and the appropriate value for a given number of periods.

4.3. Portfolio risk simulation optimization

So far, the importance of the portfolio risk of electricity generation and its impact on electricity supply has been discussed. It was

PERPUSTAKAAN NASIONAL REPUBLIK INDONESIA

Downloaded from https://academic.oup.com/ijlct/article/16/2/463/5900000 by guest on 24 March 2023

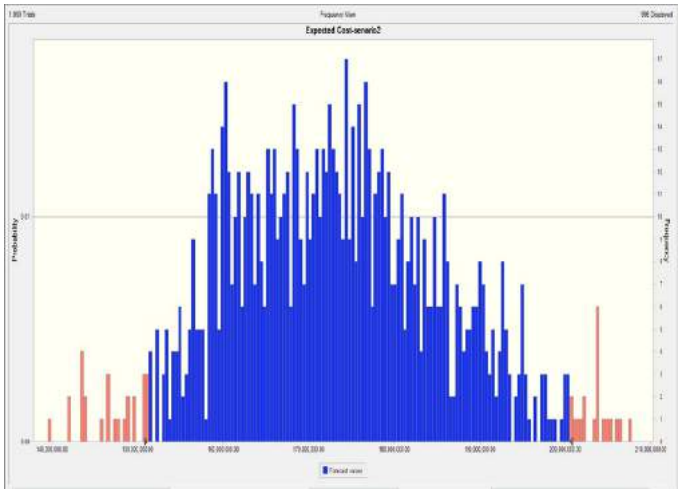

Figure 15. *Expected cost in scenario 2.*

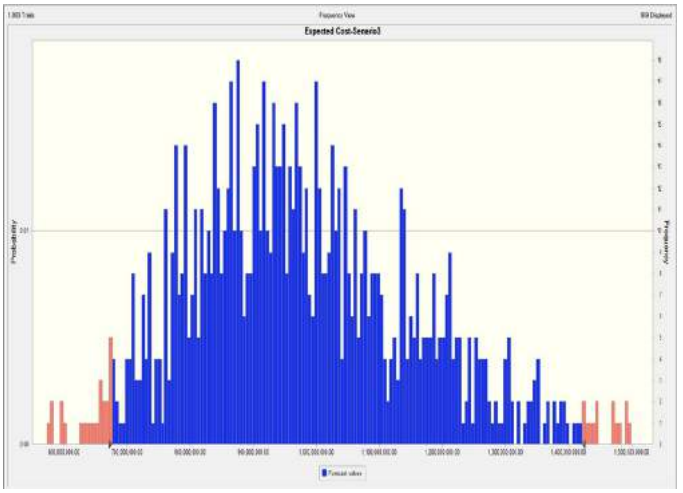

Figure 17. *Expected cost in scenario 3.*

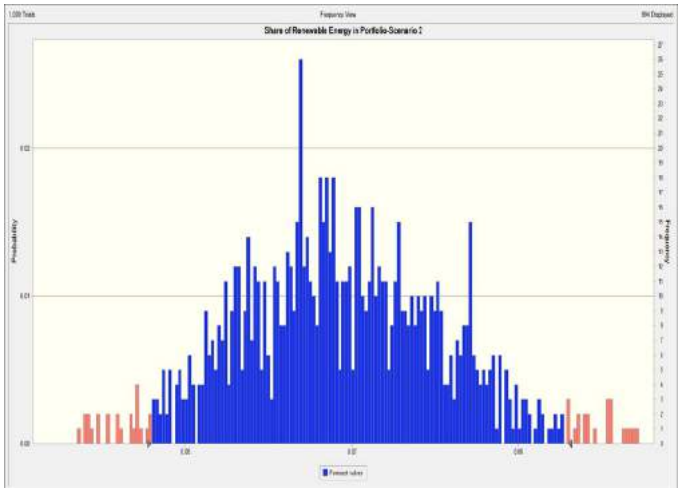

Figure 16. *Predicting the share of renewables in scenario 2.*

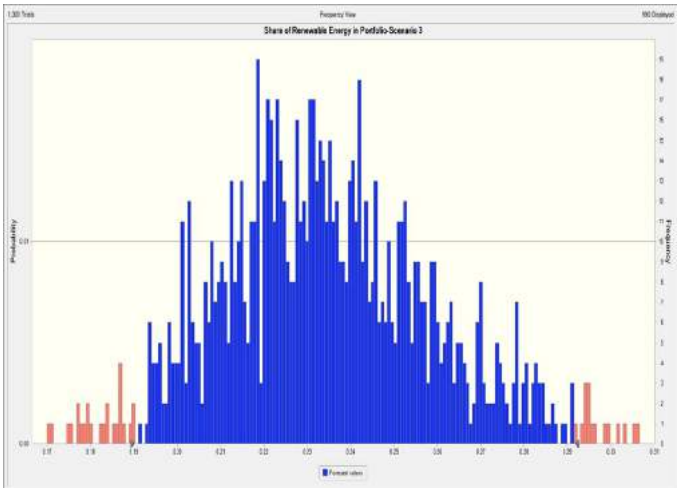

Figure 18. *Predicting the share of renewables in scenario 3.*

also found that the risk-based portfolio allows for more renewable energy in the portfolio than the cost-based portfolio. In the third set of simulations, an optimization test based on the risk simulation of the test portfolio was performed to estimate the minimum expected portfolio risk. The examination was continued in three different limited positions to analyze sensitivity. It is assumed that three main input constraints could affect the risk pattern of a renewable energy portfolio in Iran. Based on the literature review, it was identified that fossil fuel prices [24], capital costs for renewable energy production [25] and environmental costs [26] can be considered as three key factors that affect asset risk and costs. Therefore, we need to analyze the portfolio risk sensitivity using these three main input factors. Optimization was done by relying on simulations with the need for renewable energy supply exceeding 15% to make baseline scenarios. Three further tests with three different scenarios to examine the effects of these constraints on objective performance i.e. expected investment risk, and related variables such as portfolio cost were performed after the simulation. Finally, using these four simulations, four optimal risk levels were evaluated for a test portfolio. The simulation results of each of the scenarios are discussed below.

4.3.1. *Baseline scenario with minimum renewable energy supply*

The baseline scenario (first scenario) is optimized with expected investment risk E (σ_p) under the set of initial decision parameters and the minimum renewable energy commitment limit of 15% or higher. The result shows that the minimum risk trading is 0.02, which is just below the limit of the supply of renewable energy at risk factor, the export percentage of renewable energy in the reliability range of 0.95 could be in the range of 0.05–0.10 of the total national supply. Table 7 illustrates the optimization results.

This result shows that in the Iranian electricity market, the performance of the renewable energy sector is low. Now, Iran's electricity portfolio has a risk of 0.017 and a supply of 15%

Table 8. *Optimized portfolio, second scenario.*

Parameters	Objective function	Optimized value
Objective function: expected risk of the portfolio	Minimization	0.01741844
Limitation: minimum renewable technology supply	RE ≥ 15/0 10% increase in fossil fuel prices	Certainty range: 0.95 Upper limit: 0.10 Lower limit: 0.05
Expected portfolio cost	—	Certainty range: 0.95 Upper limit: 213219116 Lower limit: 139516951 (Rials per KWh)

of renewable energy. The simulation results show that Iran can reduce the expected investment risk by as much as 37% but cannot meet the minimum renewable energy supply limit (15%) (Figure 13 and Figure 14).

4.3.2. *High fossil fuel price scenario (second scenario)*

Simulation of the second scenario is essentially a sensitivity analysis that examines the huge effect of high fossil fuel prices on the risk and potential costs of investment and its impact on the amount of renewable energy supply. This scenario is simulated by a 10% increase in fossil fuel prices across the border compared to the initial scenario. As a result, there is a slight increase in expected investment risk compared to scenario 1, as well as slight changes in the amount of related renewable energy supply (Figure 15 and Figure 16). This result expressed that the rise in fossil fuel prices will not cause much change in investment risk, but astonishingly, it might not enhance the supply of renewable energy. The main cause of such behavior may be the short-term and unpredictable nature of such prices, which is not enough for investors to switch to renewable energy technologies. On the whole, it has been discovered that in periods when fossil fuel prices are high, investment in renewable energy research and development activities has increased significantly, but unfortunately not in actual energy supply. The reasons might be a relatively long period for renewable power plants to start operating since the decline in fossil fuel costs, as well as a slight effect on reducing the additional financial burden caused by rising fossil fuel prices. Another reason may be the fact that policymakers and investors are unaware of the overall benefits of renewable energy. At the policy level, this can supply more incentives for governments and legislators to create sustainable policies for the development of renewable energy. Table 8 displays the simulation results.

4.3.3. *The scenario of high costs of renewable energy capital (third scenario)*

Scenario simulation results show three different effects of increasing renewable energy capital costs against expected risks and costs. According to the simulation results, high-speed renewable energy inputs into the portfolio increase the likelihood of expected investment as well as portfolio. In Iran, solar production is still very costly; however, it has very little risk. Therefore, despite the low-risk advantage, wind and solar technologies need significant investment. In this scenario, it is tried to evaluate the effects of a 10% rise in the cost of renewable energy capital on expected investment risk (Figure 17 and Figure 18). Table 9 lists the optimal results for the key parameters. The simulation results show that production costs are predicted to increase by 10–21% and renewable energy by 12–24% in comparison with the baseline scenario. In addition, it is observed that the risk of scenario 3 is ∼2% lower than the baseline scenario.

5. CONCLUSION

It has been monitored that the risk of the portfolio can be lowered by integrating renewable energies; meanwhile, the portfolio supply costs and return can be increased. Considering the basic status of the experimental portfolio, portfolio risk can be reduced through optimization in comparison to the present status while external factors seem to be constant. This expresses the signifi-

cance of two main policy decisions in the fields of investment in the energy sector. It may benefit to reduce the portfolio risk and also supplying from a variety of renewable energy resources would lower the investment risk.

The associated risk with the power sector is rising as a result of the high status of uncertainties. This is complicated as several policies are imposed and also the necessity of environmental protection actions. This investigation was performed to illustrate the significance of explicating the portfolio risk and also to demonstrate the possible alleviation by adding renewable energy resources. Based on our obtained results, the input cost factor is a crucial item when a renewable resource is added to the portfolio and the portfolio risk is proportional to this input cost factor. Also, an increase in the CO_2 price brings about a side effect on the contribution of renewable energy in the portfolio and in addition boosts the utilization of other cleaner technologies such as liquefied natural gas and hydropower.

Based on past results, it was observed that renewable energies integration into the electricity portfolio could substantially reduce the probability of expected investment risk. As it was seen, the test portfolio risk was reduced by 37% by adding renewable energies compared to non-renewable energies. The change is significant, but it can increase expected production costs and expected return on investment too. In the original scenario where there is no significant restriction, the expected investment risk is reduced in comparison with the current condition. This illustrates the importance of two important policy decisions regarding energy investment. First, it emphasizes the advantage of reducing portfolio risk for investors; second, it suggests that using all available and diversified energy sources can help to reduce the risk. On account of the high level of market uncertainty, investing in the energy sector in today's world is at high risk. Environmental protection measures and other policies complicate the condition. To date, in the energy planning sector, the dominant paradigm of cost minimization and risk minimization has been implicit, which is reflected in the estimates. The goal of this study is to show the importance of the apparent risk of portfolios as well as the risk that can be mitigated by using of portable renewable energy. Our modeling results also illustrate that portfolio risk with a renewable energy component is susceptible to changes in input cost factors, and therefore, as portfolio cost factors increase, portfolio risk increases. In essence, the standard deviation of the price fluctuation is the key to determining the risk portfolio. Therefore, the risk of this portfolio is not sensitive to changes in fossil fuel prices and does not affect the overall price. The important conclusion can be that even if fuel price volatility is high if the price volatility is high, the investment risk will still be high, which can reduce investment in renewable energy and thus investment risk. Sensitivity investigations also illustrate that with a 10% alter in input costs, the percentage of renewable energy supply is only partially affected, but portfolio costs change from 2.5 to 21% in the scenario. It is a challenge even with the portfolio risk optimization approach to choose a style for Iran that can enhance the share of renewable energy. As shown in Table 10, only scenario 3 is capable of providing at least 15% renewable energy. Scenario 3 has the least risk compared to other scenarios. But the total cost increases by 28% compared to the current portfolio cost of Iran. So, at least 28% in cost is anticipated for achieving a low-risk portfolio with a high renewable energy

Downloaded from https://academic.oup.com/ijlct/article/16/2/463/5908000 by guest on 21 March 2023

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

source. Therefore, continued government support is required to manage the three most important subjects of cost, risk and credit. Scenario 3 is the best scenario to offer because it has the least risk and the highest share of renewable energy. It has also considered the possibility of increasing the cost of using renewable energy, which is a logical issue. So in exchange for some extra cost, a low-risk portfolio with a higher portion of renewable energy can be achieved. Achieving this optimized portfolio and reducing the use of fossil fuels in Iran's electricity portfolio will reduce emissions of pollutants, environmental pollution and other renewable energy benefits.

To conclude, a summary of the findings is as follows:

1. Reducing investment risk should be one of the clear goals of energy sector investors.
2. Adding renewable energy to the portfolio can raise the cost of portfolio production. On the other hand, it can also lower investment risk and related costs.
3. Price volatility is not the main reason for high investment risk. Therefore, this policy should be designed to stabilize such fluctuations and therefore require government intervention.
4. Changes in environmental costs have little impact on renewable energy risk and supply. Therefore, increasing environmental costs does not motivate investors to bring finance into renewable energy.
5. Considering the risk, the concept of a positive correlation between rising fossil fuel prices and investment in renewable energy may not be taken into account. This finding needs further studies on the behavior of renewable energy investments in fossil fuel prices.

6. FINDINGS

- The power sector investors should highlight investment risk alleviation.
- The portfolio's generation cost can be increased as a result of integrating renewable energies. However, this can lead to a decrease in portfolio risk and risk hedging costs.
- Variations in price state the major reason behind the risk of high investment. Hence, it is more crucial to regulate the price changes instead of decreasing or controlling the output actual price. So, government intervention through policy-making can be useful to soothe such variations.
- It has been monitored that the carbon tax's effect on the portfolio risk and also on the renewable energy supply can be neglected. Thus, increasing the carbon tax is not encouraging for investors to invest in renewable energy sectors to lower the portfolio risk.
- If the corresponding risk perspectives are considered, the conventional notion of a positive correlation between the fossil fuel price increase and investment in renewable energy may not work in reality. Further investigation into the behavior of renewable energy investment during high fossil fuel prices is needed for this finding.

Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Conflict of interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

Potential for renewable energy–assisted harvesting of potatoes in Scotland

Tariq Muneer* and Rory Dowell
School of Energy Engineering, Edinburgh Napier University, Edinburgh, EH9 2BU, Scotland

Abstract

Depleting energy resources, enhancing energy security and energy access and approaching climate change related challenges are some of the present day challenges. Against this backdrop, renewable energy (RE)-based farming has been a topic of serious discussion within Great Britain and Scotland. There are multiple advantages in the development and applications of RE micro-grids for farming communities as often they are located in areas that are quite remote and hence their energy sustainability provides security of supply. In the present article, a large-scale RE system that included solar photovoltaic and wind turbine has been critically analyzed with respect to its fractional contribution toward the total energy budget of a potato farm that produces 8000 tons of crops annually, with 4500 tons of the produce in cold storage for up to 8 months. The findings and recommendations from these case studies will help renewable energy practitioners in erecting and analyzing similar installations.

Keywords: energy payback time; renewable energy; wind energy; solar energy

1 INTRODUCTION

The earliest sources of energy that humans exploited were wind and sun. The history of wind energy may be traced up to 2800 BC when the Egyptians used it to sail their ships [1]. Likewise, solar energy use has been recorded within the historical developments of the Greek civilization. Archimedes, a Greek physicist, allegedly used highly polished shields to focus the sunlight to burn down enemy ships. Later on in the 3000 BC, the Greeks and Romans were reported to harness solar power with mirrors to light their torches. Chinese civilization documented the use of mirrors for the same purpose later on in the year 20 AD [2].

Presently employed energy systems will be unable to cope with future energy requirements—fossil fuel reserves are depleting, and climate change has become a serious issue [3]. In the year 2019, the global average atmospheric carbon dioxide concentration was 409.8 ppm and these levels are higher than at any point in the past 800 000 years [4]. In fact, the last time the carbon dioxide concentration was this high was more than 3 million years ago when the temperature was 2–3°C higher than pre-industrial era and the sea level was 15–25 m higher than today [5, 6].

Fossil fuel and nuclear energy production and consumption are closely linked to environmental degradation that threatens human health and quality of life and affects ecological balance and biological diversity. Although available only in a diffuse quantity, renewable energy is abundant, inexhaustible and widely available. These resources have the capacity to meet the present and future energy demands of the world [7]. The cost of energy generated from these renewable sources has fallen by a factor of seven in the past 7 years [8]. On the other hand, the cost of fossil fuel–produced energy is in an increasing mode.

Over the past three decades, solar and wind energy systems have experienced rapid growth [8]. This is being supported by several factors such as declining capital cost; declining cost of electricity generated and continued improvement in performance characteristics of these systems. By the end of year 2020, the number of solar photovoltaic (PV) systems in the UK had exceeded 13 400 [9] and wind energy installed capacity had exceeded 22 GW as far back as year 2018 [10]. This pattern is being duplicated the world over.

The cost of electricity from offshore wind projects completed during 2012–2014 was UK pence 13.1/kWh compared to a wholesale price of UK pence 4–5/kWh. In 2017, the Financial Times [11] reported that new offshore wind costs had fallen by nearly a third over 4 years, to an average of 9.7 UK pence/kWh, meeting the government's target of 10 UK pence/kWh 4 years early. Later in 2017, two offshore wind farm bids were made at a cost of 9.7 UK pence/kWh for construction by 2022–2023. It is expected that

a further 6 GW of clean energy is to be added to the grid by year 2025 at ~4.7 UK pence/kWh at 2019 prices [12]. These figures are lower than current generation costs for fossil fuels.

Energy is the key to economic development and sustenance of future world. With rapid urbanization and increase in aspiration of majority of population, energy demand in developing as well as developed countries across the world is ever increasing and expected to grow in future.

2 THE GROWTH OF SOLAR AND WIND ENERGY IN THE UK

It has been reported that offshore wind has the technical potential to provide 36 000 TWh/annum of energy, which is more than the current global electricity usage [13].

The world's cumulative electric power capacity for solar PV and wind reached the respective figures of 634 GW [14] and 743 GW [15]. That milestone was achieved in the year 2020 for solar and the year 2021 for wind. The comparable installed capacities in the UK for solar and wind were 13.6 and 24 GW [16]. With the respective populations for the globe and UK at 7.674 billion and 66.8 million people [17], respectively, the per capita installed capacities for combined solar and wind installations are 179 and 563 W, respectively. Clearly, the UK is leading the rest of the world by a factor of 3. Despite the UK having a weak solar resource, the per capita installed capacity is 204 W, the comparative figure for the globe being 82 W. Once again, the UK is in the lead by a factor of 2.5. At this stage, a comparison is provided for the UK's average solar income (101 W/m^2) against that for mid and lower latitude countries such as Vietnam and India (western region) and those figures are 150 and 292 W/m^2, respectively. Hence, despite the odds, the UK has taken lead once again.

The UK offshore wind sector is due to expand fast as the government aims to increase its capacity from the current figure of 24 to 40 GW within a decade. That is evident by a number of ongoing activities such as follows: (a) the company Prysmian has won a contract to supply the submarine and land export cables for the Sofia wind farm, and (b) Prysmian is also constructing a submarine cable manufacturing facility in Wrexham, England, to supply the Hornsea 2 wind farm project [18]. The latter project will be constructed some 89 km off the Yorkshire coast and will be one of world's largest wind farm with 165 Siemens Gamesa 8 MW machines spread over an offshore area of 462 km^2. The project is due for completion in year 2022.

The reason for the acceleration of growth of solar and wind electricity generation technologies is the steep price drop as Table 1 indicates.

Here, a comparison of the generation cost of fossil fuel and renewable and nuclear power plants is provided. Note that over a decade, that is, from years 2009 to 2019, while the per kilowatt hour cost of solar PV and wind have dropped by a factor of 9 and 3.3, respectively, the cost for nuclear has actually risen and that for coal has remained stable. Table 2 presents the data on the ever-falling PV module price [19]. Table 3 provides information on the UK wind energy growth and performance statistics. The capacity factor data will be of particular relevance for this article. Furthermore, note that the capacity factor is on the increase as wind turbine installations move further offshore.

The solar cell was first used in space program over 60 years ago. Then a watt of PV module cost US$1865. Taking inflation into account, the price has now dropped by a factor of more than 3300! The price for wind energy generation has also dropped, but not on the scale of solar as shown in Table 2. Note that, for solar PV, each time installed capacity doubles, the cost of electricity

falls by 36% [20]. This relationship has also been observed for wind energy developments. The levelized cost of energy (LCOE) of onshore wind has fallen by 23% while capacity has doubled; for example, see [21]. For offshore wind, the cost has dropped by 10%. The International Energy Agency has determined that the cost of offshore electricity will drop 40% more by year 2030 [22]. On the other hand, the LCOE for nuclear power plants has risen by more than 60% in the past decade.

3 ENERGY DEMAND AND RENEWABLE ENERGY GENERATION IN SCOTLAND

Scotland has an installed wind power capacity of close to 9.4 GW and generates 31.8 TWh of electricity from renewable sources, with a population of 5.454 million that translates to the energy use of 5.83 MWh/year-capita. That is in contrast to the year 2014 world average of 3.13 MWh/year-capita. The bulk of the world electricity generation includes fossil fuel plants. Table 4 presents the rapid growth of wind power plants in Scotland.

Note that with an annual-average wind speed reaching 9 m/s Scotland has one of the best energy resource of nearly 1200 W/m^2. The solar resource is much more dilute though as the receipt is around 850 kWh/m^2-day compared to certain parts of Africa, which get over 1900 kWh/m^2-day. Despite the weak solar resource, the number of solar PV plants is on the rise in Scotland as shown in Table 5.

The irony of the present situation is that those locations that have the most potential for capturing the two most promising

sources of renewable energy—solar and wind—are lacking in their effort to exploit as shown via Tables 6 and 7. Those tables are based on material presented in reference [23].

4 PRESENT INVESTIGATIONS

Large parts of land in Scotland are used for agricultural purposes. The farmers have an important role to play within the Scottish economy. As the link between climate change and energy use is becoming increasingly evident, the farmers are in the process of installing solar and wind energy conversion systems. There are many research questions to be answered though and the main purpose of this article is to address a few of them such as:

a. Based on long-term measurements, what are the seasonal and annual capacity factor for solar PV and wind energy conversion?
b. To what extent are solar and wind resources complimentary?
c. Given the high latitude of Scotland what is the seasonal influence on the above resources?
d. In an agriculture perspective, what is the present day monetary cost of solar PV and wind energy conversion in Scotland?
e. What are the solar and wind generation associated Carbon emissions?
f. What are the long-term prospects of electricity storage?

5 SOLAR AND WIND TURBINE INSTALLATION ON A POTATO FARM

5.1 Cononsyth Farms

Cononsyth Farms (CF) houses 'North Mains of Cononsyth' and 'Cononsyth Farm' (see Figures 1 and 2). The farms are a medium- to large-scale agricultural farming entity located within rural East Angus (56.613304, −2.695326). The main business activities include the growing and processing of cereal crops, oilseed rape and potatoes over a 1500 acre geographical area. Note that an 'acre'

Figure 2. *Geometrical drawing of the detail of Cononsyth and North Mains at Arbroath, Scotland F1: North Mains of Cononsyth, T: Turbine, F2 Cononsyth Farm.*

is 4840 square yards or 0.405 hectare and is a measure of area that is widely used in the British farming industry.

The farm has diversified into commercial contract drying service for oilseed rape, peas, beans, oats, wood chip and pallet logs. Various food supermarket chains purchase the products grown and supplied by the farm. In order for a supplier of significant product volumes to trade with these supermarket chains, they must demonstrate that their processes align with their carbon emission reduction strategies.

CF has installed 2.939 MW of biomass heat production, 330-kWp wind turbine and 350-kWp solar PV electrical generation; these technologies have enabled a significant de-carbonization of its energy-demanding processes. The farm is also transitioning from combustion engines with investing in a fleet of EV forklifts, which are charged utilizing onsite generated renewable energy.

The gross owned landmass at CF is 500 acres, of which 100% is irrigatable. The business produces on average 8000 tons of potatoes annually on owned and rented ground in the County of Angus. Each year, 4500 tons of potatoes are stored in cold stores at 2.5–3.5°C for 6 to 8 months of the year.

The journey to renewables at CF began in 2008 when they were introduced to small-scale wind turbines. This initiated the idea of an 11 kW Gaia Turbine. CF investigated the possibility of a wind turbine and inquired into an early small scale renewable incentive scheme known as Renewable Obligation Certificates (ROCs). However, CF understood that to significantly reduce the farms' energy bills, a larger turbine would be required.

In 1 April 2010, a new UK Government–led renewable incentive scheme was introduced for generation of less than 5 MW rating. The scheme introduced is called the Feed-in-Tariff. From the launch of the scheme in 2010, the incentives were reduced by the process of degression until the closure for new applications in March 2019.

CF initially proposed a 500-kW turbine; however, it was advised that planning would be too high of a risk. The farm decided on a 330-kW turbine manufactured by a German company called Enercon. Enercon turbines were known to be of high reliability due to their non-gear generating technology.

Planning was submitted to Angus Council in June 2010 and was approved in December the same year. The turbine, which was one of the largest in Angus at the time, received no objection from 12 consultees. The application was seen to be consistent with the local development plan of the area, and no material considerations of sufficient weight would warrant the refusal of the application. The turbine was installed in 2012 and achieved an incentive payment of 23.5 p/kWh of electricity generated.

Also in 2010, CF enquired into the possibilities of roof-mounted solar PV. At the time, CF experienced difficulty getting Angus Council to agree to this principle as no roof-mounted solar PV system application had been submitted to them previously. The farm found a way around this by drawing panels on the roof of a new cold store warehouse extension. CF inadvertently got planning approval for the first 50-kW solar PV system in 2011, obtaining an incentive payment of 31 p/kWh generated. As it is index linked, the incentive payment is 38.5 p/ kWh. The installed JA Solar JAP60S01 270 W polycrystalline PV modules sit on the

PERPUSTAKAAN NASIONAL REPUBLIK INDONESIA

roofs that are at an angle of 15 degrees from horizontal, with an aspect of 5 degrees East of South.

The de-carbonization of heat on the farm was initiated in 2013, with the installation of a biomass burner with floor-drying infrastructure to dry all the cereals grown by the business. Furthermore, biomass burners were installed in 2014, 2015 and 2016. CF identified a business opportunity for supplying dried woodchip to neighboring farmers with their own woodchip burners. CF was one of the only authorized suppliers in the area. The demand for woodchip lead to a gradual increase in biomass heat generation. March 2021 saw the installation a 900-kW woodchip burner. The farm now has 2.939 MW of heat generation from three units manufactured by an Austrian company ETA with thermal capacities of 199, 350 and 500 kW. Two other units in use were manufactured by German manufacturer Heizomat with respective thermal capacities of 990 and 900 kW.

The buildings at North Mains of Cononsyth are used for potatoes and potato box storage, grading and grain handling. The largest buildings are potato cold stores. The potato cold stores are energy demanding and operate for 6 to 8 months of the year. The stores have the capacity to store 1500 tons and maintain a temperature of 2.5–3.5°C.

All solar systems operate with no service fee; however, they are periodically reviewed to ensure performance is as expected. A service call out will be initiated if there is a notable decrease in energy generation.

In October 2012, CF installed a 330-kWp turbine after gaining planning consent in 2010. The turbine secured a Feed-in-Tariff of 23.5 p/kWh and paid back in just 4.5 years. The turbine generates electricity that is consumed directly on-site for the cooling demand of the 8000-ton crop grown annually. Although, the energy generation is 300% of the annual consumption of the farm, some 34% of the annual energy use is still imported. That is due to a lack of synchronicity between wind energy conversion and demand.

Figure 4. *The 330kWp wind turbine at North Mains of Cononsyth Date of installation: October 2012.*

The wind turbine is serviced under an agreement called Enercon PartnerKonzept contract. The annual cost of the service contract is €10 000 up to 7 years then €20 000 up to 15 years. Then after, the service fee is negotiable. As the turbine is now 8 years old, the service fee is now in the second phase.

5.2 Renewable energy generation at CF

In the year 2019, the North Mains solar PV plant was further enlarged, significantly, by addition of another 250 kW. That

completed facility is shown in Figure 3. The total PV capacity at CF complex is thus 350 kW, split between Cononsyth (300 kW) and North Mains (50 kW). Each 15 minutes, the data-logger records the minimum, maximum and the average power output for the three power-plants. The three solar power-plants are the 50 kW each, installed in year 2011 at the Cononsyth Farm and the North Mains of Cononsyth, and the additional 250 kW installed in year 2019 at Cononsyth Farm. All PV plants are in good order, and their maintenance is backed up by a service contract.

The frequency of data collection from the wind turbine is 10 minutes, and among the parameters recorded are wind speed at the height of wind turbine nacelle (82 m), wind direction and minimum, maximum and average power output of the turbine and energy generation. Figure 4 shows graphical views of the CF wind turbine. It has to be reiterated that the turbine is in good order and its maintenance is backed up by a different service contract.

Tables 8 and 9 present performance of the wind turbine on an annual and monthly basis, respectively; the latter being for 1 year, 2015, which was most productive. The capacity factor is a good measure to assess the performance of a power plant. The capacity factor indicates the fraction of the time that the power plant was delivering at full capacity or the ratio of actual energy generated to the ideal value of energy that may be generated provided the plant ran at full capacity for the entire duration. While the capacity factor is of a high order, perhaps reaching a value of 0.9 for nuclear and fossil fuel plants, its value is much lower for renewable energy plants. It may be noted that in Table 8 no capacity factor has been reported for year 2012. This is due to the fact that the wind energy generation start date was 8 November 2012. Due to incompleteness of the year, the capacity factor for 2012 is not comparable to the corresponding value from other years. The average wind speed shown for year 2012 is also quite high (9.1 m/s) as the data are skewed heavily toward winter months with associated higher wind speeds. A few interesting points that may be picked up here are as follows: (a) in years 2015 and 2017, the average wind speed is identical, and yet the average power in year 2015 was 13% higher; (b) likewise, in years 2018 and 2019, the same phenomenon occurs, that is, identical wind speeds and yet year 2018 delivers power that is 19.5% higher; (c) compared to annual average, the two winter months of November and December have a wind speed average that is 37% higher.

The disparity of the energy yield for the years 2015 and 2017, and for the years 2018 and 2019 may be investigated further via Figures 5 and 6, and Figures 7 and 8, respectively. These four plots are explored furthermore. The first two plots, Figures 5 and 6, show the annual mean wind speed and capacity factor and a scatter plot that relates capacity factor to mean wind speed, respectively. Both figures indicate that for a given annual wind

PERPUSTAKAAN NASIONAL REPUBLIK INDONESIA

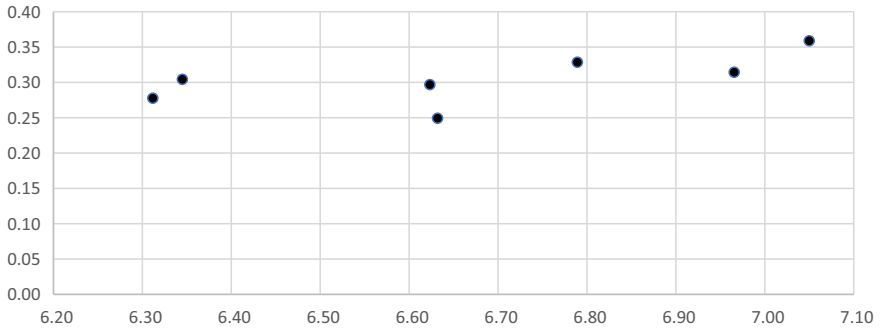

Figure 6. *Annual-averaged capacity factor versus wind speed for Arbroath x axis: wind speed, m/s; y axis: capacity factor.*

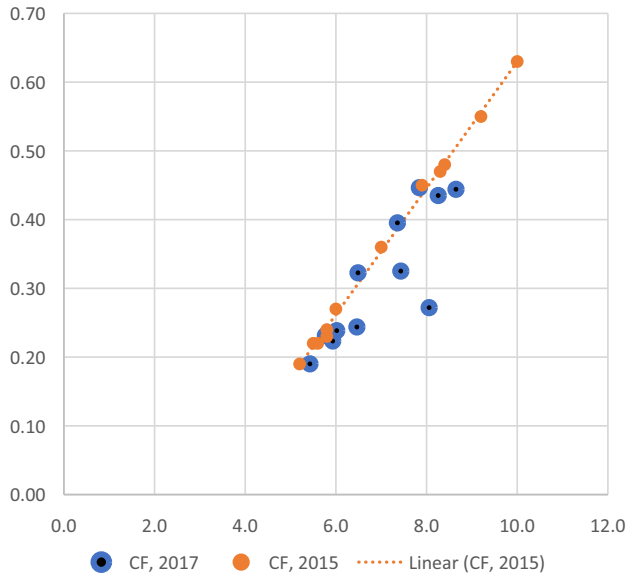

Figure 7. *Monthly-average wind turbine power versus wind speed for years 2015 and 2017 x axis: wind speed, m/s; y axis: capacity factor*

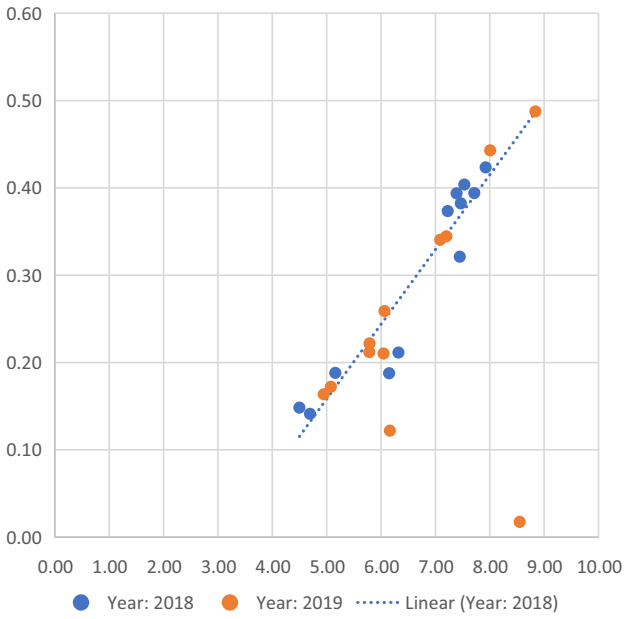

Figure 8. *Monthly-average wind turbine power versus wind speed for years 2018 and 2019 x axis: wind speed, m/s; y axis: capacity factor.*

speed the turbine delivers different values of capacity factor. That could be due to three reasons: (a) the mean wind speed is a combination of many instances of either low wind that lies below the cut-in speed of the wind turbine, which is around 4.5 m/s and that would reduce the capacity factor; (b) instances when the turbine was shut down due to storm conditions or mechanical breakdown; or (c) a combination of the latter two factors.

Close inspection of the dataset revealed that item (c) was the cause of the aforementioned phenomenon, that is, identical average wind speed and yet very different values of capacity factors. Note that the slope of the best-fit line for data from year 2015 (Figure 7) and year 2018 (Figure 8) indicates the same trend.

Hence, the conclusion is that the turbine is well maintained and has an annual high capacity factor of 0.36. Figure 9 provides further evidence in this respect, that is, the frequency of occurrence of a given wind speed is similar for the 2 years under discussion—2018 and 2019. The considerable departure of capacity factors for the latter two years is therefore mainly due to turbine downtime.

Tables 10 and 11 present data for solar PV performance in a manner similar to Tables 8 and 9. Once again note that the solar PV data were logged from 30 September 2011 onwards and hence in Table 10 no information is presented on capacity factor for that year. Furthermore, for the year 2021 the data were only available up to the month of April and hence the capacity factor is not available for the latter year. It is clear from the tabular information presented so far that at Arbroath the capacity factor for wind energy conversion is three times more compared to solar PV. That is on an annual basis.

On a monthly-averaged basis the wind/solar capacity factor ratio is much higher in winter months with low sun angle and shorter days. Hence, if a solar PV plant is to compete with wind turbine, the capacity of the PV plant ought to be at least three times more. Figure 10 presents such information for the combined total energy of a 330-kW wind turbine and 1-MW solar PV plant. Note that the energy delivery profile is now much more stable as

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

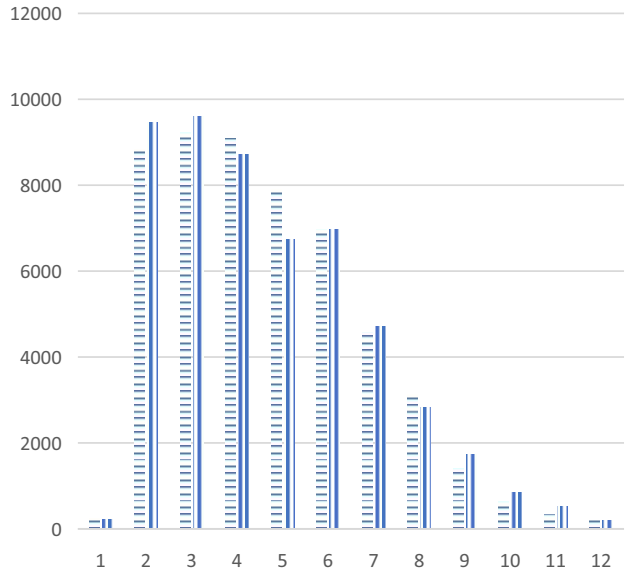

Figure 9. *Frequency of wind speed (m/s) for years 2018 and 2019.*

opposed to sole delivery from either a wind or a solar plant. The low performance of solar plant in winter months is subsisted by high wind energy delivery and vice-versa in summer.

That information is further enhanced via Table 12, which provides the average, the standard deviation and coefficient of variation (CoV) for solar, wind and combined plants. Note that for the combined plant the CoV drops to only a third of the value for solar and half of what the wind turbine offers, thus making it a stable entity.

The element of wide variation of energy delivery is inevitable in both solar and wind energy. Figures 11–13 present the daily variation of energy delivery from wind, solar and combined plants. The plots have been made for two months—January, a winter month, and September, a late-summer month. Once again, the advantage of the combined plant is obvious. The usefulness of such plots is that they enable design analysis of the storage that would be required for any given load profile. Renewable energy plants will need to overcome the intermittency related issues to become truly popular and useful. A great deal of work is ongoing with respect to battery and other forms of energy storage. That item shall be briefly explored in the following section.

Figure 14 provides a comparison of the turbine power delivery—the manufacturer's provided acclaimed performance is compared against measured power for two years, 2015 and 2019. The year 2015 presents data when the turbine was just over two years old, whereas 2019 data are for the machine when it was 7 years of age. No significant departure of actual power delivery is seen, thus validating the quality and maintenance of the machine.

6 EMBODIED CARBON ANALYSIS

With the rapid decline in the cost of PV modules and wind turbine electricity generation, the key decision parameter will be the emissions associated with any energy generation technology. Both solar and wind are in good stead as the present analysis will show.

In Lifecycle Assessment (LCA) studies, the energy payback time (EPBT) for any product is calculated as total primary energy used in the manufacture of the product divided by the annual energy generated by the product. For renewable energy products or systems the EPBT will be among other things, dependent upon the energy intensity of available electrical and thermal energy, and the climate as the latter will dictate the solar or wind energy resource. Within the context of the Scottish climate, Muneer *et al.* [24] carried out an LCA on an Edinburgh solar PV installation. Using the data provided in references [25–28], Muneer *et al.* [24] showed that the embodied CO_2 in the given solar PV system that included the mono-crystalline modules, inverters, cables and the supporting structure was 44 g CO_2/kWhe. The EPBT was found to be 8 years for Scottish climate.

More recent such work has been carried out by Kim *et al.* [29] and Ludina *et al.* [30].

Kim *et al.* [29] have shown that the EPBT for the mono-crystalline PV facility in South Korea was 2.97 years. The embodied CO_2 in the South Korean PV system that, once again, included the mono-crystalline modules, inverters, cables and the supporting structure was reported as 25 g CO_2/kWhe and the Carbon intensity of the mains electricity grid as 495 g CO_2/kWhe.

Ludina *et al.* [30] have provided LCA for rooftop mono-crystalline silicon PV in Southern Europe (solar irradiation of 1700 kWh/m^2/year). The reported EPBT was 2.5–3.0 years in year 2000 and 2.1 years in 2006, which decreased to 1.75 years in 2009. The gradual decrease is due to improvements in manufacture of PV modules that use less Silicon as time progresses. The latter EPBT figure of 2.5–3 years for Southern Europe ties closely with the 8 years EPBT for Scotland, reported by Muneer *et al.* [24]. The Scottish solar irradiation is 822 kWh/m^2/year, which is roughly half the receipt for Southern Europe, and hence the EPBT is doubled for Scotland.

Incidentally, Ludina *et al.* [30] have also quoted the GHG emissions data for wind power as having a range of 6.2–46 g CO_2-eq/kWh.

The work of Lenzen and Munksgaard [31] has shown that the capacity factor for wind turbines lie in the range of 10–50%,

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

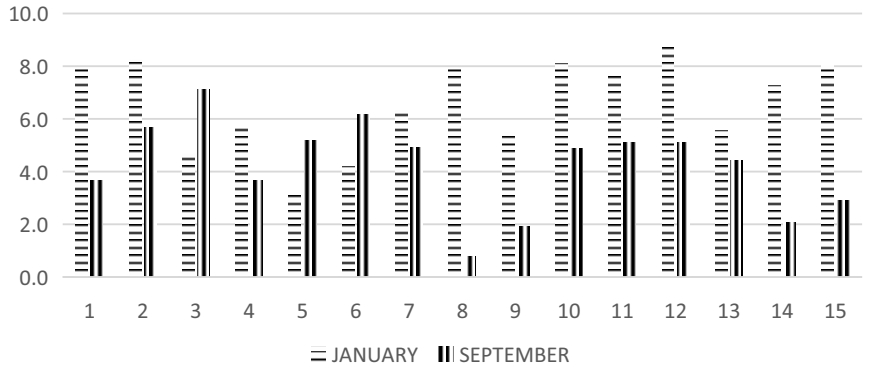

Figure 13. *Energy generation (MWh) of the combined 1 MW solar and 330 kW wind power plants for year 2015 x axis: day number.*

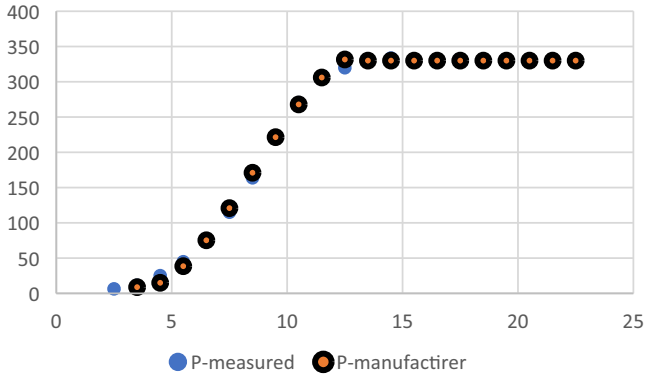

Figure 14. *Comparison of actual and manufacturer-claimed power delivery of the 330 kW wind turbine. X axis: wind speed, m/s; y axis, kW.*

although most modern machines have that range narrowed down to 20–35%. We have seen in the present analysis that under Scottish climate the capacity factor could be much higher, particularly during winter months.

Based on the works of Krohn [32], Gurzenich *et al.* [33], Schleisner [34] Ancona and McVeigh [35] and Wibberley *et al.*. [36], the lifetime of modern wind turbines has been shown to be between 20 and 30 years. Furthermore, work carried out under the aegis of Vestas wind turbine manufacturers [37] has shown that even after the latter time period the only components that may need replacement are the moving parts: generator, gearbox and blades. The 330-kW Enercon machine under discussion seems to validate the above claim with only the blade covering starting to show signs of wear and tear after 9 years of operation.

The works of Pick and Wagner [38] carried out for a 500-kW machine, and Tremeac and Meunier [39], for a 4.5-MW turbine have shown that respective embodied energy quantities are 3948 GJ and 70 152 GJ.

Research undertaken by Crawford [40] on the lifecycle audit of embodied energy of an 850-kW and a 3-MW wind turbine included a detail assessment of four major components—foundation, tower, nacelle and rotor. His results indicate that the embodied energy of the 850-kW machine was 34 574 GJ/MW and that for the 3 MW machine was 30 725G J/MW.

More recently, Smoucha *et al.* [41] carried out carbon analysis for 14 wind turbines that ranged from 50kW to 3.4-MW output suggests and confirms the works of Pick and Wagner [38] and Tremeac and Meunier [39], that is, the higher rated machines have higher carbon content per MW but the payback time drops with capacity. Smoucha *et al.* [41] found that the higher rated wind turbines had higher embodied Carbon per kW capacity, e.g. whereas an 80 kW machine had 58 tonne of Carbon, a 3 MW machine had 1,046 tonne embodiment. However, the latter research team has note that the payback time of larger machines was much shorter due to their higher capacity factors. That may be explained to the siting of higher capacity machines in open spaces such as offshore locations and higher hub height.

The work of Smoucha *et al.* [41] may be summarized with respect to embodied energy; thus, the embodied ton of CO_2 for 80-, 100-, 250- and 500-kW machines are 58, 61, 148 and 274, respectively, and their EPBTs expressed as a percent of the machine lifetime are 2.6, 2.2, 2.1 and 2. Interpolating for the 330-kW Enercon machine presently under discussion leads to an embodied 190-ton CO_2 and an EPBT of 3.1% of the lifetime.

7 LARGE-SCALE ENERGY STORAGE: PROSPECTS AND CHALLENGES

7.1 Electricity storage in electric batteries

The rapid rise of electric vehicle (EV) fleet around the globe presents an opportunity for large-scale storage of off-peak electricity from solar and wind. The trip efficiency of electricity storage and its reuse is very high, and thus this technology is appealing. On the downside, however, the large-scale mining of lithium and cobalt from a very limited number of countries in South America and Congo and the very serious environmental impact will be a big challenge. It is clear that off-peak storage will have to be via a number of alternate technologies.

In Scotland alone, with a population of 5.4 million people, the number of EVs is now over 7000. The average Li-ion battery has a 40-kWh capacity, and that figure is rising for newer models of

PERPUSTAKAAN NASIONAL REPUBLIK INDONESIA

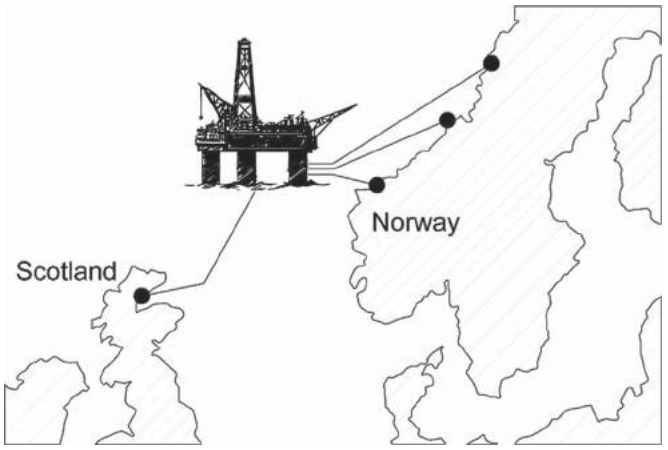

Figure 15. *Schematic for hydrogen production and transmission from Norway to Scotland*

vehicles that are appearing on the market. That translates into a storage capacity of 280 MWh that is available in the present time. However, by the year 2040, when most of the present automobile fleet of 3 million is replaced in favor of EVs, the storage capacity will exceed 180 GWh. The latter figure assumes an average battery capacity of 60 kWh for the EVs by year 2040. Note that the projected storage capacity of 180 GWh is over 40% of the daily electricity use in Scotland and should therefore suffice as a solution to the intermittency issue of renewable energy. However, there are other solutions available as well such as pumped hydro and hydrogen production via electrolysis of water. The pumped hydro is an established technology in Scotland with one of the first such schemes having been built in the year 1896 by Alcan for their aluminum smelter near Foyers, Inverness. Pumped hydro requires a large land area and further exploitation of this technology seems unlikely. However, hydrogen production is on the up and shall be discussed in the following section.

7.2 Electricity storage via electrolysis of water

The Scottish Port of Cromarty Firth is in the process of setting up agreements with the company Gen2 Energy of Norway to develop a project that will eventually lead to import of renewable electricity generated hydrogen into the UK. Figure 15 shows the schematic for hydrogen production and transmission.

The plans include setting up of an industrial scale electrolyser. The time scales demand that clean energy will be available by the year 2023. This will be demonstration of a large-scale, international project that will include the production, storage and supply of green hydrogen to Scotland, the rest of Great Britain and Europe. The plans include shipment of hydrogen by land and sea. Note that the thinly populated northern regions of Norway have an excess of renewable energy and present constraints on introducing that energy in the electricity network and thus the production and shipment of hydrogen presents a unique opportunity [24].

8 DISCUSSION

In Section 5, an initial analysis of the energy conversion performance of the 330-kW wind turbine and 50-kW solar PV facility on Cononsyth farm was presented. In this section further discussion is provided with the five research questions that were raised in Section 4 addressed expressly.

Tables 8 and 9 respectively presented data on annual and monthly wind speed, average power and capacity factor. Inter-annually, the wind speed is fairly consistent, varying between 6.3 and 7 m/s. The average and standard deviation of wind speed are 6.7 and 0.3 m/s, respectively. The average power delivered from the 330-kW machine varies between 82 and 118 kW. The corresponding capacity factor varies from 0.25 to 0.36 with mean and standard deviation of 0.33 and 0.03. Note that the ratio of standard deviation to mean is 10% on an annual basis. On the other hand, on a monthly basis, obviously, the variations are much more pronounced with a low capacity factor of 0.19 in September that rises to a high value of 0.63 in January, with a mean of 0.36 and standard deviation of 0.14 for the 12-month data. That is a reflection of the associated wind speeds in those months—5.2 m/s in September and 10 m/s in January.

The installed cost for the 330 kW Enercon wind turbine was £850 000. Reference [41] cites the life of modern wind turbines as 20–30 years. Assuming a 25-year life of the machine and referring to Table 8 for the energy delivery profile the monetary cost of the wind generated electricity works out as 3.56 UK pence/kWh or 4.03 US cents/kWh. The latter figure compares well with data provided in Table 1, which quote the cost of wind energy conversion as 4.1 US cents/kWh. The embodied EPBT for the wind turbine under discussion has been shown to be 3.1% of the lifetime (see Section 6).

Likewise, Tables 10 and 11 presented data for solar PV. On an annual basis the capacity factor has a range of 0.09–0.108, a mean value of 0.1 and standard deviation of 0.01. On a monthly basis, however, the variations for solar are much, much higher as would be expected for such a high latitude location as Arbroath—the capacity factor varying 0.01–0.18, a mean of 0.109 and a standard deviation of 0.063 for the 12-month data. The coefficient of variation (ratio of a standard deviation to mean) is now 58%. The corresponding figure for wind was 0.4, which indicates a much more stable resource.

Table 12 presented results for a hypothetical farm, which has the same 330-kW wind machine but with a much more enhanced solar PV facility of 1-MW capacity. In this case, the combined resource has a much more stable energy delivery with the coefficient of variation being only 20%. That is because of the complimentary nature of wind and solar—the former being a strong and stable resource in the winter months and vice-versa for solar. The latter is the case particularly at high latitudes with a large swing of availability of wind and solar throughout the year.

The actual installed cost quote that was received by the farm owners is £0.812 per watt. At the present conversion rate that is US$1.13 per watt. For the energy delivery profile shown in Table 10 and assuming a 20-year life of the PV installation, that

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

works out at 4.54 UK-pence/kWh or 5.13 US-cents/kWh. That figure also compares well with data of Table 1, which showed a PV-generated electricity price of 4 US-cents/kWh. The embodied energy payback time for PV under Scottish climate was shown to be 8 years, which also has good agreement with reference [30].

In Section 7 two different technologies were presented for electricity storage that has to come into play given the intermittent nature of solar and wind resource. In view of the steep rise of EV sales and increasing amount of research being carried out on behalf of large corporations and governments on hydrogen generation and storage, the long-term prospects of electricity storage are indeed favorable.

9 CONCLUSION

CF is located near Arbroath in Scotland. In the years 2011/2012, the farm installed 50-kWp capacity of solar PV and a wind turbine of 300-kW capacity. Energy generation data were collected respectively at a frequency of 15- and 10-minute intervals. The following conclusions are drawn from the analysis of per 7 years of data.

The annual capacity factor for solar PV and wind energy conversion were in the range of 0.09–0.108, a mean value of 0.1 and standard deviation of 0.01 for solar PV and 0.25–0.36 with mean and standard deviation of 0.33 and 0.03 for wind. The monthly capacity factor for solar varies widely between 0.01 and 0.18. For wind the range of monthly capacity, factor was 0.19–0.63. It was found that the solar and wind resource in Scotland are advantageously complimentary with the output of the combined solar/wind plant having only a third of the coefficient of variation compared to solar or half of that for wind. The abovementioned wide variations in the monthly capacity factor are primarily due to the high latitude of Scottish locations.

A monetary energy and embodied carbon-related assessment was also carried out. It was found that the per kilowatt-hour cost of electricity from solar and wind were, respectively, 5.13 and 4.03 US cents. The payback time for wind turbine was found to be 3.1% of the lifetime of the machine or, in other words, 9.3 months. For solar PV the figure quoted was 8 years payback time.

Renewable energy plants will need to overcome the intermittency related issues to become truly popular and useful. A great deal of work is on-going with respect to battery and other forms of energy storage. A review of that work was presented and critically discussed.

Professor Tariq Muneer is a senior academic who is based at Edinburgh Napier University in Scotland. Professor Muneer has also been employed both by the government and industry as a consultant on a large number of engineering projects. Professor Muneer has been awarded several prestigious awards including the Royal Academy of Engineering Industrial Fellowship (2000–2002), the Royal Academy of Engineering Engineers Secondment Overseas (1995), the Leverhulme Trust (1989) and the University College, Oxford/General Electric Company, (1989) Research Fellowships. He is also the recipient of the Osmania University's Karamat Jung Gold Medal (1974), CIBSE Carter Bronze Medal (1990), CIBSE Napier Shaw Bronze Medal (1999), Millennium Commission's Fellowship Award (1999), Walsh-Weston (Society of Light & Lighting, London) Award (2002), Services to Industry Group's Proof of Concept award (2003) and the Scottish Green Energy, Highly Recommended Best Renewable Award (2006).

Professor Muneer is the author of 10 books and over 280 articles that have attracted over 4000 citations. He is also an editorial board member of the following three journals:

'Energies', published by the Swiss-based MDPI publishing house.

Sustainable Cities and Society, published by Elsevier.

Advisory Board Member: International Journal of Synergy in Engineering and Technology (IJSET).

Professor Muneer has also served as guest editor for the following three special issues of 'Energies' journal.

1. Recent Advances in Sustainable Buildings: Space Heating, Space Cooling and Lighting https://www.mdpi.com/journal/energies/special_issues/recent_advances_in_sustainable_buildings
2. Practice and Innovations in Sustainable Transport https://www.mdpi.com/journal/energies/special_issues/practice_and_innovations_in_sustainable_transport
3. Development of Sustainable Energy: Generation Technologies and Concepts https://www.mdpi.com/journal/energies/special_issues/generation_technologies_and_concepts

Professor Muneer is a visiting professor at the University of Granada, Granada, Spain and University of Maribor, Celje campus, Slovenia (2013–2023).

Rory Dowell has a Bachelor of Engineering degree in Energy and Environmental Engineering (Honors) from Edinburgh Napier University and a Masters of Sciences degree in Management from the University of Edinburgh. Rory is an energy consultant for a renewable consultancy in Edinburgh. Rory also works on renewable investment, engineering activities and project management. Rory has a strong interest and understanding of rapidly emerging renewable markets within the agriculture communities of Scotland and has spoken about his experiences at numerous events.

Renewable Energy Systems: Optimal Planning and Design

Yosoon Choi

Department of Energy Resources Engineering, Pukyong National University, Busan 48513, Republic of Korea; energy@pknu.ac.kr; Tel.: +82-51-629-6562

Renewable energy systems have emerged as a key solution to mitigate the impacts of climate change and meet the growing demand for energy in a sustainable way. The application of renewable energy technologies has the potential to reduce greenhouse gas emissions, promote energy security and access, and foster economic growth and job creation. As such, the development and deployment of renewable energy systems have become a top priority for many countries worldwide.

The Special Issue of *Applied Sciences* on renewable energy systems brings together a collection of original research and review articles that address various aspects of renewable energy systems. The contributions cover a broad range of topics, including solar, wind, and wave energy systems, and energy storage, grid integration, policy and regulatory frameworks, and socio-economic impacts.

One of the key themes that emerge from the articles is the importance of technological innovation, research, and development to drive the advancement of renewable energy systems. Several articles highlight the potential of new and emerging technologies, such as community battery energy storage systems, offshore wind and wave energy integrated stations, and renewable energy-based charging stations for electric vehicles, to enhance the efficiency and cost-effectiveness of renewable energy systems. Alrashidi [1] proposes a bi-level optimization method based on a neural network optimization algorithm for the efficient planning of multiple community battery energy storage systems (BESS) in low-voltage distribution systems with high residential rooftop photovoltaic (PV) units. The method optimally places and operates BESS collectively at a distributed system level, using linear programming to minimize the daily voltage signal. The simulations show the efficacy of the proposed method in enabling utilities to determine the optimal location, capacity, and number of BESS to regulate the voltage within acceptable bounds under the influence of network topology, load profiles, and the amount of PV power.

Le and Nhieu [2] propose a novel dual-side behavioral spherical fuzzy multi-criteria decision-making approach to determine high-efficient and sustainable locations for offshore wind and wave energy integrated stations (WWS). The proposed method combines quantitative indicators and qualitative criteria to provide recommendations for appropriate WWS locations. The research provides efficiency and sustainability positioning maps and compares findings with current development projects, plans, and policies in Vietnam for validation. Alkawsi et al. [3] review studies related to renewable energy-based charging stations for electric vehicles, covering aspects such as resources, potentiality, planning, control, and pricing. The study clarifies challenges and proposes suitable solutions for this type of charging station. The paper aims to provide an overview of charging electric vehicles through renewable energy and establish the ground for further research in this vital field. Pintér et al. [4] explores the potential of utilizing the battery energy storage systems of small electric boats in Lake Balaton, Hungary, as a means of energy storage to mitigate fluctuations in power generation. The paper presents the potential utilization of Europe's significant network of sea and inland recreational ports for the purpose of energy storage and explores the volume of energy storage potential in small electric boats, which may facilitate the creation of new types of flexibility services related to energy storage.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

The innovative novelty of this study is that it regards small, fully electric boats not just as vehicles, but also explores their energy storage potentials.

Others explore the challenges and opportunities of integrating renewable energy sources into the grid, and the role of smart grid technologies and energy management systems in optimizing energy consumption and reducing waste. Thiesen [5] highlights the insufficiency of existing energy system modelling and the literature covering the reduction in power system inertia resulting from the increasing share of grid frequency converter-connected renewables. The work proposes an open-source energy system model that incorporates minimum system inertia constraints, wind turbines, and battery storage systems as carbon dioxide-free sources for synthetic inertial response. The results indicate that integrating system inertia constraints has a high impact on system costs, and investments in additional storage units providing inertial response may be necessary. Sierra-Aguilar et al. [6] proposes a new model for solving the security constrained unit commitment problem in power systems, which addresses the challenges of reducing computational load and modeling uncertainty of intermittent generation and demand. The proposed affinely adjustable robust model uses linear decision rules and a novel method for evaluating N-1 security constraints, which increases computational efficiency when transmission line contingencies are considered. Monte Carlo simulations demonstrate the effectiveness, feasibility, and robustness of the proposed model.

Another significant theme that connects the articles is the need for supportive policy and regulatory frameworks to facilitate the deployment of renewable energy systems. Munkhbat and Choi [7] used a GIS-based approach to identify suitable sites for large-scale solar PV power plant installations in Mongolia. Seven criteria were used to collect data for each cell, and an analytical hierarchy process was used to determine the weightings of these criteria. Results showed that the central region of Mongolia should be prioritized for installing PV power plants due to the presence of good sites and high demand for electric power in the region. Seo and Suh [8] investigated 100 smartphone applications (apps) developed for the solar PV energy sector and categorized them based on their functions. The apps were grouped into seven categories, including computation of sun position, PV system optimal settings, PV site investigation, potential assessment of PV systems, environmental and economic assessment of PV systems, monitoring and control of PV systems, and education and learning for PV systems. The study discusses the limitations of app implementation in solar PV and implications for future improvement.

In sum, the Special Issue of *Applied Sciences* on renewable energy systems provides valuable insights into the current state and future prospects of renewable energy systems. It underscores the importance of interdisciplinary and cross-sectoral collaboration, and the need for continuous innovation, policy support, and stakeholder engagement to enable the transition towards a sustainable energy future.

Tidal and Ocean Current Energy

Rafael Morales [1,*] and Eva Segura [2]

[1] Escuela Técnica Superior de Ingenieros Industriales de Albacete, Universidad de Castilla-La Mancha, 02071 Albacete, Spain
[2] Escuela Técnica Superior de Ingeniería Industrial de Ciudad Real, Universidad de Castilla-La Mancha, 13005 Ciudad Real, Spain; eva.segura@uclm.es

Renewable energy resources (for example, wind, solar or ocean currents, among others) possess an enormous potential, owing to the fact that they are a pollution-free and inexhaustible resource. However, although the technological developments for harnessing energy from the wind and the sun have been studied long-term, the technology for harnessing energy from tidal and ocean currents is still in its infancy.

In this Special Issue, we present contributions that focus on research in support of the development of tidal and ocean current energy in order to outline the current state of the art and highlight the emerging trends and challenges in this field, ranging from mathematical modeling to methodological aspects. We expect that these contributions will help in future designs of technologies for harnessing energy from tidal and ocean currents. The five papers in this Special Issue address the knowledge gap towards the development of tidal and ocean current energy technologies.

Yan et al. proposed in [1] the design of swept-back symmetrical airfoil blades based on three kinds of swept design methods, and discussed the influence of different designs on the hydrodynamic performance of the adaptive variable pitch blade. The software of SolidWorks was used to build the 3D model of the hydraulic turbine. Based on the preprocessing software ICEM CFD, the solver Fluent, and the post-processing software CFD-Post, axial thrust coefficient, energy acquisition characteristics, and starting torque of the turbine models were analyzed and discussed. In addition, physical model experiments of the selected model were carried out to verify the performance of the numerical simulation.

Cai et al. developed in [2] a novel output power internal control strategy based on a pseudo-tip-speed ratio and an adaptive genetic algorithm (PTSR-AGA) to improve the anti-interference ability and reliability. The proposed control scheme consists of two parts. The first part proposes the PTSR method for the maximum power point tracking (MPPT) to predict the tidal stream turbine's operating point, which contributes reducing the logical errors assigned to swell disturbances. The second part designs an AGA for the optimization of the pitch controller to conduct its angle delay. A reduced pitch control strategy was applied to the preprocessing of the pitch controller to reduce the mechanical wear over the rated power. The comparative simulation results validated that the tidal stream turbine system could obtain a higher power efficiency of energy capture and a smoother power output with the proposed control strategies at full range of tidal current speeds.

Schmitt et al. presented in [3] several field tests of a tidal turbine, performed using a self-propelled barge in real tidal flow and still water conditions, that were compared to a towing tank test. Factors influencing the performance characteristics, such as the choice of velocity sensor, vessel handling, and data processing techniques were investigated in this paper. Direct comparison with test results of the exact same turbine obtained in an experimental test facility further confirmed that field testing with robust data analysis capabilities was a viable, time- and cost-efficient alternative to characterize tidal turbines.

Zhou et al. numerically studied in [4] the key structural parameters of the spring–mass system that govern the dynamics of the double-elastic-constrained flapping taking the rigid

NACA0012 airfoil as the object. A two-dimensional numerical model, based on the CFD software FINE/Marine, was established to investigate the influence of the spring stiffness coefficient, frequency ratio, and damping coefficient on the motion and performance of the flapping hydrofoil. This study demonstrated that when the structural parameters were adequately adjusted, the power factor exceeding 1.0 had been achieved, and the corresponding efficiency was up to 37.8%. Moreover, this system could start and work within a wide range of damping coefficients. However, the hydraulic efficiency and power coefficient are sensitive to the change in damping coefficient, so it was very necessary to design an appropriate power output. Lastly, the most obvious parameter affecting the energy acquisition performance was the spring stiffness coefficients. Frequency ratios in the two directions had little influence on the peak value of the power coefficient, but they will cause the change of damping coefficients of the peak point. The key structural parameters studied in this paper provided a useful guideline for an optimized design of this interesting system through searching for the best performance.

Liu et al. investigated in [5] the influence of swept blades on the performance and hydrodynamics of the bidirectional horizontal-axis tidal turbines (BHATTs). A three-dimensional (3D) numerical model based on OpenFOAM was adopted to simulate a full-scale BHATT. The numerical framework was validated using two well-known experiments, and the mesh convergence was taken into consideration. The results indicated that the forward- and backward-swept blades had a limited impact on the performance and hydrodynamics of the BHATT.

Author Contributions: R.M. and E.S. jointly developed the concept and co-wrote this editorial. All authors have read and agreed to the published version of the manuscript.

Funding: This Special Issue has been supported by the postdoctoral researcher contract for scientific excellence within the framework Plan Propio de I+D+i of the Universidad de Castilla-La Mancha, co-financed by the Fondo Social Europeo (FSE) and the Fondo Social Europeo Plus (FSE+) [grant number 406].

Acknowledgments: The authors wish to thank all contributors to this Special Issue. Wind Energy and the Energy Transition: Challenges and Opportunities for Mexico

Abstract: We present a review of wind energy development in Mexico, factors hampering this development, and proposals for solutions to address this hampering. This review is relevant in the context of climate change mitigation strategies and the achievement of the United Nations' sustainable development goals. Wind energy can be harvested at competitive costs to solve society's energy poverty and climate change problems. Firstly, we present the current wind energy installed capacity and wind power generation status globally and in Mexico and discuss why Mexico is lagging behind, particularly since 2020. Despite this lag, several state governors are still considering wind energy developments. The current economic context is then considered, with community wind energy as a solution forward for wind energy development, using a successful case study from the UK that has addressed energy poverty and provided an additional income source for an island community. Any community energy project using wind as its main energy resource relies on accurate wind energy assessment in its feasibility analysis. Thus, an evaluation of different wind energy atlases for Mexico was performed, which showed that models considering microscale processes could lead to a relative difference of more than 50% when compared to those that do not consider them. This led to the conclusion that microscale effects must be considered in wind energy characterization models. Furthermore, it is acknowledged that wind faces other challenges, such as the effect of future climate change scenarios, grid planning, and vulnerability and risk associated with tropical storms, which can be substantial in Mexico. Solutions are proposed in the form of possible wind power generation scenarios, planning and implementation of centralized and distributed transmission lines, and possible wind siting and technological choices to reduce the vulnerability and risk to tropical storms. Finally, we close with some future perspectives for researchers and decision-makers. The main conclusions are that sustainable growth can only be compatible with a transition to renewable sources of energy, energy community projects can address energy poverty and achieve sustainable development goals, wind energy feasibility studies need to include microscale effects, return of investment can be improved by siting the wind farms in regions of low vulnerability and risk to extreme events, and high-voltage transmission lines are crucial for sustainable development, even with the important role that distributed systems play. Finally, turbine growth and materials recycling, among other factors, must be considered when assessing the environmental impacts of wind farm decommissioning.

1. Introduction

Energy production from wind turbines constitutes a suitable alternative to fossil fuels. From utility-scale plants to small turbines in residential areas, technically-viable wind solutions have become widespread. Moreover, costs of onshore and offshore wind energy have declined by 39% and 29%, respectively, between 2010 and 2019 [1], making wind energy more affordable and helping reduce global energy poverty [2]. The technological maturity, combined with the economy of scale, gives wind energy a unique advantage over other renewable energy sources. As an affordable clean energy [3], it can play a synergetic role and help achieve several of the United Nations' sustainable development goals (SDGs), such as improving energy wealth, providing employment and economic growth opportunities, reducing inequality, promoting innovation [4], and fighting climate change [5,6].

Achieving transport and energy production decarbonization by 2050 will be crucial to comply with the terms of the Paris agreement [7], and reach net zero CO_2 emissions [8,9]. Although renewable technologies infrastructure still requires fossil fuels, life cycle greenhouse gas emissions are significantly lower for technologies powered by renewable resources than those powered by non-renewable ones [10]. Renewable energy corporations have been criticized for perpetuating social injustices [11] or using vast land extensions for energy production. However, when comparing normalized land use for both renewable and conventional energy sources, it has been found that some types of renewables, like PV, actually use the least amount of land [12]. Tröndle [13] showed that onshore wind has the highest land requirement if the spacing is considered, when compared to rooftop Photovoltaics (PV), utility-scale PV, and offshore wind, with the latter three being "no-regrets" options when the aim is to reduce the spatial extent of land-based renewables. Moreover, PV and wind power plants can be located in multi-use brownfields [14], and recent research has shown that land requirements of renewables can be reduced with little effect on costs [13].

Additional cost reductions can be achieved with hybrid systems and by addressing electricity generation and water desalination [15]. Studies on solar-wind independent systems are common, but not those integrating access to electricity with hydrogen storage and desalination. Although this technology would help provide electricity and potable water for communities in semi-arid coastal regions, the reliability of the system and its cost-benefit advantage, particularly at small scales, is unclear. Rajewski et al. [16] showed that wind turbines and crop co-location, such as corn and soybeans, were beneficial for the crops because turbines slow down the wind but increase turbulence. Therefore the wind interacts more with the crop, possibly increasing evaporation from the crop or moving carbon dioxide down into the crop. The turbines delay dew formation at night, which is beneficial to the crops because dew may cause fungi issues. Farmers can therefore get a stable income from the lease of the land, and as turbines take up a small proportion of the land, they can carry on with their farming activities. Moreover, because of the effects of the turbines on the microclimate around the crops, their crops will be healthier with present turbines than without.

From a socio-economic and rural sustainability perspective, a recent study by Mills [17] showed that wind energy development might help reverse the rural population loss observed since agriculture's industrialization. The economic impact of leasing the land to a wind farm is easy to measure. The income from land leasing is reinvested into agricultural activities by the farmers, but the social impact is more nuanced. An important finding of the study was that a farmer with a wind farm lease is significantly more likely to have a succession plan in place as well. In other words, the supplemental income provided by the wind turbines helps convince the younger generation that it is worth staying on the farm.

In relation to the impacts of adopting utility-scale wind energy in the fight against climate change, the immediate consequence of renewable energy production is the reduction of CO_2. However, the impacts go beyond just the reducting CO_2 emissions, with studies showing that large-scale wind farms can increase rainfall and change vegetation

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

growth patterns in arid lands [18]. Energy-intensive industries such as steel and iron are ideal clients for utility-scale wind. They have proactively researched and implemented green energy generation models to reduce their greenhouse gas emissions [19], without jeopardizing operations and securing the jobs provided by industry. The impacts of climate change can be reduced significantly thanks to the transition of these industries to clean energy sources.

As the Danish experience of the 1970s demonstrated, common citizens and small to medium-sized businesses can also contribute to the energy transition by organizing into energy communities. These energy communities play crucial active roles in the energy markets: they contribute two to eight times more to the local economy than non-local competitors, while efficiently decarbonizing the economy. A report by consultants CE Delft, based on the European union (EU), showed that energy communities could produce up to half of the EU's clean energy by 2050 [20]. Moreover, energy communities advance new forms of justice and democracy in practice [21]. However, it is unclear how they can gain a foothold on the prevailing structures of the renewable energy economic system [22].

This review paper is motivated by Mexico's lag in implementing onshore and offshore wind energy projects. By analyzing global and national installed capacities and their annual growth in the past years, we show that in the case of Mexico, such lag can be explained by the current Mexican economic and political context. Mexico's current policy discourages private investment in Renewable Energy projects, as the government argues that private projects perpetuate social injustice. To rebut this, we discuss an example of a community energy project that provides a solution to energy poverty and addresses the social injustices wind energy developers have otherwise caused in some parts of the country. Community energy projects based on wind energy, like any other wind energy project, require a characterization of the wind resources that is as accurate as possible at a local scale, i.e., the microscale. This improved accuracy should be reflected in what we commonly refer to as wind energy atlases. However, not all wind atlases incorporate the microscale effects, particularly those generated from weather models. Several wind atlases are available for Mexico; here, we show that the Global Wind Atlas produced by the Danish Technical University (DTU), which considers meso-microscale coupling for wind speed predictions, can be used to preliminary investigate wind energy potential. Wind faces other challenges, including the effect of future climate change scenarios, grid planning, and vulnerability and risk associated with tropical storms. Wind energy can combat climate change, but the degree to which it can achieve this depends on a number of factors, e.g., future generation scenarios; technical, ecological, and economic restrictions; the degree of development of the transmission lines; and the effects of hydro-meteorological extremes on wind farm siting and choice of technology. Other issues and solutions regarding the sustainable development of wind energy, e.g., territorial planning [23] and economic feasibility of wind energy projects for different site and technology choices based on the local wind climate [24,25], should be addressed too. We recognize the importance of these issues, as can be inferred by some of the examples we will use, but they are site and project-dependent. Here we will focus mostly, on problems and possible solutions with implications at a countrywide scale.

This work is organized as follows. In Section 2, the World's current status in installed capacity (IC) is discussed, and the evolution of IC in Mexico in the last few years is presented and discussed in relation to the energy policies implemented by the previous and the current federal administration. We selected some wind farm samples to show the spread of important wind energy resources throughout the Mexican territory. In Section 3, Mexico's lag with respect to global trends is explained within the context of the current government's political and economical approach. In Section 4, we present the case of an energy community in North Uist, an Island of the Outer Hebrides (in Scotland, UK), where a wind turbine project was implemented for community consumption and energy export. This has been included to show a current community energy success story using wind turbines and consider this a possible avenue in other countries, such as Mexico. In

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Section 5, we present different wind energy resource evaluation methods and highlight the advantages of models that integrate microscale effects into mesoscale wind energy resource assessments. Sections 6–8 focus on the challenges posed to wind energy development by future climate change scenarios, grid planning, and the vulnerability and risk indexes associated with tropical storms. Finally, in Section 9, long-term perspectives and concluding remarks are provided. It is worth noting that although the study focuses on Mexico, it can be replicated for any other country or region of the World.

2. Status of Installed Capacity and Changes in Energy Policies

Global renewable energy status reports show that the global IC in the wind energy sector increased between 52 and 64 GW annually from 2014 to 2019 [26–28]. In 2020 and 2021, it increased by 95 GW and 102 GW, respectively, thus reaching a total of 845 GW by 2021. In 2020, 35 GW [27], and in 2021 almost 19 GW [28], of the total IC corresponded to offshore wind farms. Figure 1 shows global installed capacity between 2002 and 2021 [28,29].

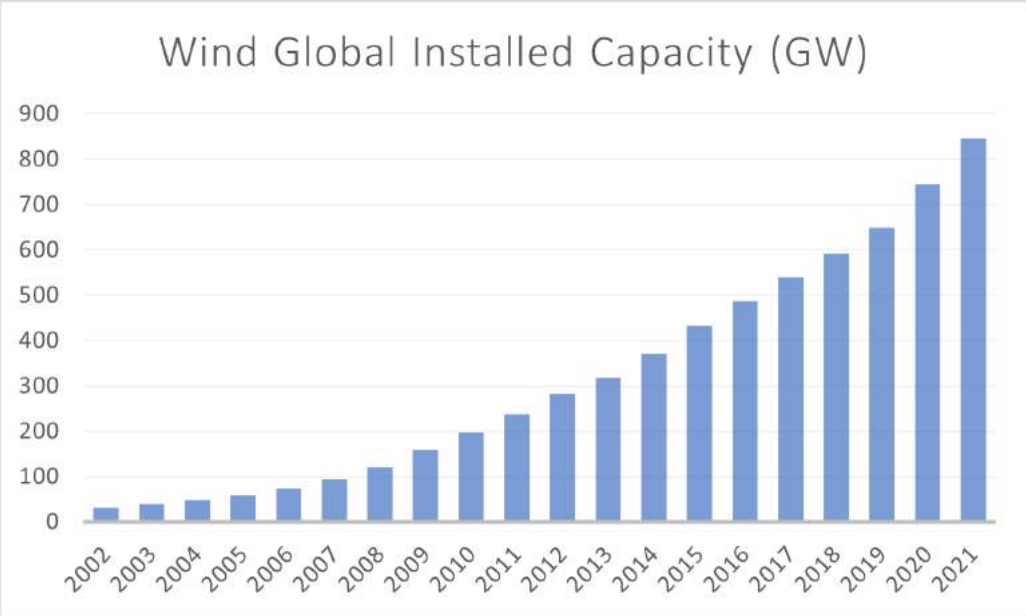

Figure 1. Global wind installed capacity from 2002 to 2021. Data taken from [28,29] (accessed on 1 March 2023).

Wind farms are operating in more than 90 countries; in 30 of them, more than 1 GW of IC has already been achieved. It is worth mentioning that by 2017, several European and some Latin American countries produced more than 10% of their energy from wind. Denmark and Uruguay, in particular, produced almost 60% and 40%, respectively, of their electricity from wind. The case of Denmark is noteworthy; since the 1970s, a number of wind farm projects have been developed by local energy cooperatives. This significantly increased the contribution of wind energy to the country's energy matrix and improved the level of acceptability of wind turbines as a source of energy among the Danish population.

Figure 2 shows the wind power generation (TWh) for all IEA member states from 2010 to 2021 [30], and Mexico's wind power generation (GWh) for the same years [31]. While IEA members' global wind power generation grew steadily between 2010 and 2021, we notice growth fluctuations in wind power generation for Mexico over that same period, with a growth deceleration from 2018 onwards.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

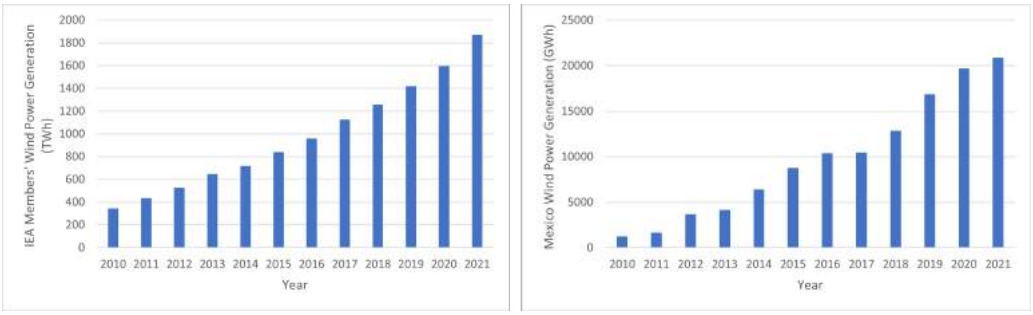

Figure 2. IEA members' total wind power generation in TWh (**left**), and Mexico's wind power generation in GWh (**right**), from 2010 to 2021. Figures generated with data from [30,31], respectively.

In 2018, 95% of new energy installations were exploiting renewable energy resources [32]. Furthermore, in 2018, the EU generated 362 TWh from wind energy farms, which increased to 458 TWh in 2020, corresponding to an increase of 25% in 2018 [33]. Wind energy covered 13.7% of the EU's energy demand in 2018, and 16% by 2020. It is expected that from now until 2025, some European countries will lead the wind energy development market, with the following IC (in GW): UK, 18; Germany, 16; France, 12; Sweden, 7; The Netherlands, 6 [33]. In 2020, Finland installed wind energy plants with the largest wind turbines on land, with an average rated power of 4.5 MW, while the smallest turbines, with an average rated power of 2.2 MW, were installed in the UK [33].

Offshore wind turbines are increasing continuously in rated power. While the largest turbine in 2017 had a rated power of 8 MW, some prototypes now reach 16 MW [34]. On the other hand, offshore wind turbines, such as the Heliade-X, have increased their capacity factors to up to 64%, compared to 25% to 42% that offshore wind turbines could achieve in the 1970s and 1980s [33]. From an economic point of view, each percentage increase in capacity factor represents a return on investment of approximately seven million dollars [35]. Thus, an increase to 60–64% in capacity factor represents an increase in the return on investment of 100 to 300 million dollars per turbine. Finally, wind turbines with hubs at higher heights and with longer blades might operate under conditions where wind speeds are less variable and under low turbulence, making energy production more predictable [35]. These facts illustrate some of the benefits of the economy of scale. Unfortunately, Mexico is far behind in wind development and deployment, with only onshore wind farms in operation and no clear offshore wind farm plans.

We now focus on historical and current onshore wind energy development in Mexico. In 2017, wind energy plants in Mexico produced 10 TWh, corresponding to 3.44% of the global annual energy production (AEP) from wind for that year. With 45 wind farms distributed throughout the national territory, only 3% of the total annual energy produced by the country was wind generated [36]. Table 1 shows some of the major wind energy plants currently in operation in Mexico. Compared to the largest wind farm in the world, Hornsea 2, off the Yorkshire coast, with 1.3 GW of IC, the largest wind farms in Mexico have installed capacities three times smaller. This helps put into perspective the degree of development of wind energy, or lack of it, in Mexico.

In 2017 the total installed capacity (IC) in Mexico was 75 GW, with only 29.5% of that based on renewable energy sources. This total IC had increased to 83 GW by 2020 [36,37], or a 10% growth in three years. The wind energy IC was 4 GW in 2017 and 6 GW in 2019, representing an increase of 50% in only two years. However, we must highlight that this growth took place mostly in 2018, under a regulatory policy framework promoting renewable energy projects. During 2020 and 2021, regulatory changes were introduced that hampered investments in the renewable energy sector. In fact, between 2019 and 2020, the wind energy sector only grew by 0.76 GW in IC [38]. Despite the regulatory measures introduced by the federal government, some states with the highest wind energy potential, such as Tamaulipas, have carried on planning a significant growth in IC, from 1.5 GW in 2020 to 1.9 GW by 2025 [38].

In Mexico, only 10% of the total energy consumed was provided by renewable energy sources in 2020 [27]. Without considering hydraulic dams, renewables contributed 12.8% of the country's IC in 2017. This had increased to 18.4% by 2020. The IC of solar photovoltaic grew from 214 MW in 2017 to 5149 MW in 2020, being by far the renewable energy source with the largest annual growth rate, and positioning Mexico among the four most important photovoltaic energy developers in Latin America [27]. There was also a large increase in thermal solar energy projects in the industrial sector, positioning Mexico as the global development leader. Mexico also became the leader in Latin America in new geothermal developments, and sixth worldwide, with an IC of 9.9 GW at the end of 2020 [27].

3. Wind Energy Development in the Current Economic Context

From January 2020 to date, a global pandemic has slowed all the world's economies, dislocated industries and logistical and commercial production chains while simultaneously demonstrating the interdependence between countries and the importance of the energy sector on the economy. This economical crisis has been exacerbated by climate change impacts that are more noticeable and extreme than before. In this economic, energetic and environmental crisis, developing renewable energy sources, such as wind, plays a critical role.

Mobility and economic activities were significantly reduced during the pandemic, which caused a large reduction in energy demand. Consequently, we saw a negative price of crude oil in April 2020. The pandemic caused a contraction of the gross domestic product of −8.5% [39], an inflation rise of 7.45% [40], and a lower tax return on oil exports. On the other hand, the war in Ukraine has also contributed to oil price increases and inflation in 2022. Mexico has always exported oil and used oil revenue as a lever for economic growth. However, basing the country's development on fossil fuel exploitation is incompatible with climate change mitigation strategies. Energy is one of the strategic productive factors for all economies and having energy availability at affordable costs favors economic growth. However, if this energy comes from fossil fuels, GHG emissions will be generated, remaining in the atmosphere and causing global warming.

Renewable energy resources play a critical role in reducing GHG emissions and are compatible with green economic growth. The International Energy Agency estimates that over the next 30 years, radical changes will occur in the global energy sector toward a growth path with neutral emissions (net zero). In line with this perspective, daily oil production could go from 90 million barrels in 2020 to 22 million daily in 2050. These changes in the energy sector would be accompanied by an expansion of new electrical capacity, going from 261 GW in 2020 to 1000 GW in 2030, of which an additional 600 GW will be from photovoltaic solar power and 400 GW from wind power [41].

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

The investments and costs of renewable energies will be an essential variable to achieve a path of economic growth compatible with sustainable development goals. The capital invested in renewable energy projects was just over 1 trillion dollars (2019 USD) during the period 2016–2020 and is expected to increase to 4 trillion dollars by 2030 and until 2050 [41]. During the last decade, a downward cost trend has been observed in the renewable energy sector, being an economically viable option even without any subsidy. Indeed, the weighted average leveled costs decreased in 2020 in solar thermal (16%), photovoltaic (7%) and wind energy both onshore (13%) and offshore (9%) compared to the year 2019, making them economically viable options [42]. The energy technologies that will allow a future with economic growth and neutral emissions already exist, their costs have decreased in recent years, and they should be installed in the country.

4. Community Wind Energy: The Case of North Uist, an Outer Hebrides Island

The North Uist project is a community-led, utility-scale wind energy development that demonstrates that well-organized communities can achieve their energy autonomy and turn into prosumers, both to produce energy for their homes and businesses or trade energy for other goods [43]. The project started operating in August 2019, and two ENERCON 0.9 MW community turbines generated 6129 MWh per year until September 2020, close to the forecasted yield of 6370 MWh per year. enough to cover the needs of the 1600 residents with an average household electricity consumption of 3831 kWh [44]. This project was chosen because of its success as a community project, and because it paves the way for similar projects of rural communities in other countries, particularly in Mexico.

The feasibility analysis of North Uist Wind was based on future community demands of energy, using clean energy technologies at the commercial readiness level, for the benefit of the local community and the environment [43]. The feasibility study included three types of energy: marine renewable energy, wind energy, and bioenergy. The Uist Wind partners analyzed the impacts and consequences of different projects at different scales: small-scale projects that can reduce the costs of energy consumption and at the same time reduce greenhouse gas emissions and large-scale projects that can become a sustained source of income for the community. The impacts focused on benefits and employment opportunities within reach of the community based on the renewable energy resources available on the island. This preliminary study, which includes from the start a socio-economic analysis, allows for prioritizing and planning different community-led projects, beginning with those with the best return on investment from the economic, ecological, and social perspectives.

The first issue considered in the planning and prioritization process concerned the population. The population density, settlement size in terms of the number of residents and a number of households, and settlement spread were critical in the analysis. These considerations help determine the optimal IC according to the distance from the grid and the nearest human settlements' size.

The second issue considered from the start was the presence of extensive industrial states in given areas. In coastal regions such as North Uist, industrial states include ports, warehouses, food processing plants, commercial fisheries, government offices, tourists, sports or retirement centers, or schools, to name but a few. The energy and heating needs of such users may be substantial. In locations with extreme environments or poorly insulated buildings such as North Uist, an eight-bedroom hotel may require between 25 and 35 thousand liters of fuel oil per year and have a demand for 30–45 kW in either heating or air conditioning, equivalent to 272–408 MWh per year [43].

The third issue concerns energy poverty and is directly linked to SDG7, i.e., universal access to clean and affordable energy. The feasibility analysis included a population census where the percentage of the population who live in energy poverty, i.e., those who used more than 10% of their net income to cover their energy needs, was determined [43]. In Mexico, alternative definitions of energy poverty based on relative social well-being have been proposed [45]. Still, the definition based on net income is non-ambiguous and thus more transparent to the need for action. Either way, renewable energy projects' ultimate aim

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

should empower the communities through democratic access to energy, energy services, and energy poverty abatement.

The fourth and final issue concerns possible development restrictions for conservating endangered species and natural protected areas. Which government and community authorities are in charge of managing these areas? How restrictive are the laws in relation to the development of renewable energy projects in these areas? Highly-restrictive areas need to be mapped out and identified as no-tolerance regions. Such is the case for areas of importance for the conservation of birds, or AICAs [23], for example. In marine areas, regions of no-tolerance include those for critically endangered marine species, such as the *Vaquita Marina* porpoise in the Gulf of California [46].

If there are only isolated settlements in a region, distributed small-scale renewable energy networks may be considered without any (or very few) negative environmental impacts. In this case, residential-scale turbines could be installed on rooftops or other locations with known wind speed classes and adapted to local conditions. Adopting this strategy would still solve energy poverty and GHG emission issues, albeit on a smaller scale. It should be noted that an isolated utility-scale turbine does not pose a significant threat to wildlife, even when installed in an AICA. If the turbine is still deemed unsafe for some endangered species after a thorough analysis, mitigation strategies must be put in place, or the turbine installed elsewhere.

Achieving project development milestones depends on flawless planning, thorough environmental and social impact studies, and focused community consultations. The fact that a project is community-based should be advantageous since the staff promoting it are part of the community and therefore know the region and the community's needs. However, there will always be a need to dialogue and negotiate with associations and local authorities to carry out the planning correctly and improve the chances of success. Table 2 summarizes some possible impacts that McLean and Robertson [43] considered, indicating who would be the possible stakeholders and responsible authorities in the case of Mexico.

Table 2. Potential impacts of onshore and offshore wind energy parks, based on the analysis by McLean and Robertson [43].

Problem	Description of Approach	Actors Involved
Landscape problems (sound or visual)	The local managing authorities (LMA) evaluate the project proposal for potential impacts and determine the methodology used to quantify the impact, whether they are acceptable, and if not if mitigation strategies can be implemented. LMAs in charge of historical heritage will provide information on cultural and historical areas that can be affected.	LMAs, INAH, other historical, archaeological, or cultural associations.
Ecological and geophysical studies	Geophysical issues include effects on the hydrological cycle, on fracture or subsidence of soils, the risk of hurricanes or other extreme events on wind power plants, and the environmental impacts of offshore turbines for sea projects, among others. Ecological issues include effects on flora and fauna, especially on birds and bats.	LMAs, CONANP, HEIs and NRCs, CONABIO, SEMARNAT, recognized national associations of geophysicists (e.g., the UGM) or ecologists.
Radar and aviation	The movement of the turbine blades can interfere with RADAR signals. Large turbines can interfere with aeronautical operations, particularly near airports or military bases.	SEMAR, MOD, DGAC, AAC

5. Wind Energy Resource Evaluation for Mexico

Wind energy resource analysis and pre-feasibility studies are based on the yearly (or longer) distribution of wind speed, U, and wind direction, θ, the wind power density (WPD), and the AEP. Wind speed and direction are normally displayed as time series at selected locations and heights or as interactive maps, as in the Global Wind Atlas (GWA): https://globalwindatlas.info (accessed on 29 December 2022). The GWA was produced from wind data generated by the Weather Research and Forecasting (WRF) numerical weather prediction (NWP) model, with initial and boundary conditions provided by the ERA5 reanalysis. This model was used to simulate the atmospheric flow at 62 vertical layers on a global domain with a 3 km $\times$ 3 km horizontal grid spacing covering all the land surface and up to 200 km into the ocean. The topographic information and the output generated with an NWP (in particular, the velocities) can be used to generalize the wind field. This generalized wind field can be interpreted as the wind that would prevail without the influence of local topographic features. This generalized wind field is again reduced/downscaled in temporal and spatial scales to grids with much finer horizontal spacing (in the order of tens of meters), using the microscale models in the WAsP software developed by DTU (see https://www.wasp.dk/, accessed on 3 March 2023), and in combination with high-resolution topographic data at local scales. The data shown on the GWA website is integrated into a horizontal grid with a spacing of 250 m $\times$ 250 m. This procedure (generalization and downscaling) is known as the European Wind Atlas method [47]. Dörenkämper et al. [48] followed a similar procedure for producing the New European Wind Atlas (NEWA). The GWA also shows the yearly-averaged wind speed maps at 50, 100, and 200 m, representing past, present and future hub heights.

Wind energy resource analysis tools are provided on the GWA website. Figure 3 shows the annual WPD at 100 m above ground level (all heights are hereafter above ground level) for Mexico. A location with a WPD larger than 1000 W m^{-2} is considered to have great wind resource potential. Such WPD values are found in some Mexican sites, as illustrated in Table 3.

Table 3. Locations around Mexico with great (larger than 1000 W m^{-2}) wind resource potential, as measured with their yearly wind power density (WPD) at 100 m above ground. Based on the Global Wind Atlas (https://globalwindatlas.info/en, accessed on accessed on 29 December 2022).

Location	Short Name	WPD (W m^{-2})	Latitude	Longitude
La Rumorosa	BC	2486	32.54	−116.03
Tamaulipas	Tam	2451	24.641	−99.076

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

The regions mentioned in Table 3 appear in Figure 3. The geographical coordinates show approximate locations within each of the mentioned Mexican states. They should not be used for wind farm planning purposes unless supported by a microscale wind energy analysis and on-site measurements.

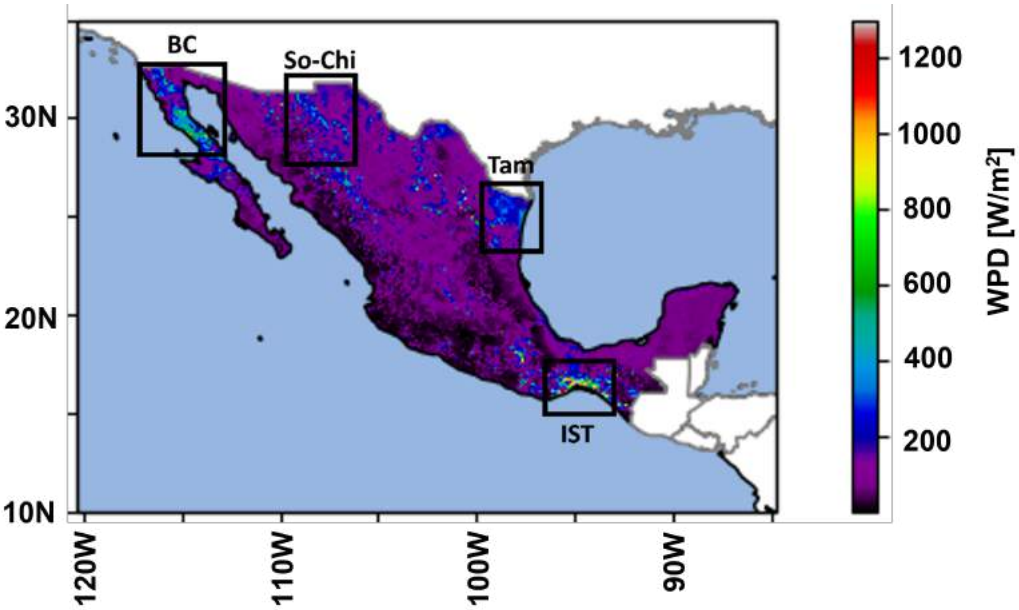

Figure 3. Annual wind power density (WPD) at 100 m based on the GWA 3.0 data available at https://globalwindatlas.info/ (accessed on 29 December 2022). The rectangles show regions with high wind power density (see text for details).

Wind speed predictions may vary significantly depending on the wind data sources. In order to illustrate this, we used three different sources: the GWA 3.0 previously presented; the WINDToolkit, a database with current wind predictions and future scenarios developed by the U.S. National Renewable Energy Laboratory (NREL) with a horizontal grid spacing of 2000 m (see https://www.nrel.gov/grid/wind-toolkit.html, accessed on 1 June 2020); and a yearly-averaged WPD map developed by VESTAS with a horizontal grid spacing of 3000 m (see https://maps.nrel.gov/gst-mexico, accessed on 1 June 2020). While the wind energy maps generated in the GWA 3.0 are produced using WRF and WAsP, those using the NREL and VESTAS data are produced with the WRF model only and therefore do not consider microscale effects on the wind, which are crucial for accurate predictions of local winds.

Figure 4 shows the maximum relative difference between the VESTAS and the WINDToolkit wind speed predictions relative to the GWA. The blanked-out areas are regions where the difference is larger than 50%, and include, for example, the central part of the Isthmus of Tehuantepec, the Pacific Coast from Jalisco to Oaxaca, as well as some areas in the Coast of Tamaulipas. This is a substantial area of the country, and most importantly, these are areas generally known for having good wind energy resources [24]. Note that values larger than 30% can also be observed throughout the country near the coast and inland. It is also noteworthy that there is no correlation between large percentage differences between atlas products (Figure 4) and WPD (see Figure 3): regions with either low or high WPD can present high percentage differences between atlas products. Therefore, all wind energy assessments, especially those based on NWP models that do not consider microscale effects, must be interpreted cautiously.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

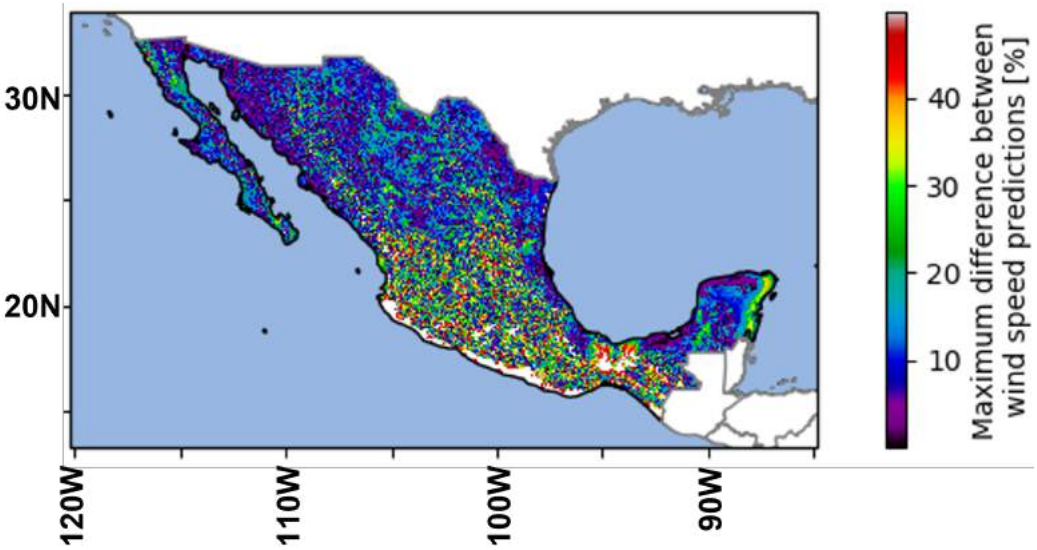

Figure 4. Maximum relative difference between wind speed estimated by the WINDToolkit and VESTAS in relation to that of the GWA, shown in Figure 3.

These maps show regions where the probability of finding a site with commercially-exploitable wind resources is high. However, it is essential to quantify the wind resources with in situ wind speed measurements taken for at least one year and at heights close to the proposed hub heights, to have robust and reliable wind climatologies that are useful for the wind energy sector, and to assess the accuracy of the numerical models at those heights. If installing meteorological towers with sensors at different heights from the ground to hub height or higher is impossible, wind lidars can be used [49]. Wind lidar measurements have been performed in Mexico since 2017, and high-quality meteorological towers were installed as part of the Mexican Wind Atlas (MWA) project. The MWA project involved the installation of 10 towers, with cup anemometers and wind vanes measuring both wind speed and direction at 20 m intervals, between 20 m and 80 m.

In summary, a wind energy atlas is not a simple map of mean wind speed and direction at a given height for a given region on the Earth. The wind field needs to be validated against observations, wind speed and direction need to be provided at several heights, and a broad database that allows for more detailed computations needs to be made available [50]. Moreover, the numerical simulations must include a microscale evaluation of the wind energy resource. Numerical datasets based on mesoscale models that omit such evaluation, like the VESTAS and NREL datasets used here, have mean relative differences in wind speed relative to a meso-microscale coupled model that can be over 50%, with differences above 30% in a significant percentage of the land surface.

6. Possible Generation Solutions: Contrasts and Limitations

To evaluate possible wind energy generation scenarios, we used the atlas of regions with optimal wind energy resources (AZEL). The AZEL was developed with input from a team of experts who identified access to transmission lines as the most important limiting factor. Distance to the national grid is crucial for a project to be commercially viable. Based on this, four different scenarios were proposed. The data for the four scenarios, SCE1 to SCE4, was downloaded from https://dgel.energia.gob.mx/azel/ (accessed on 4 February 2021). The SCEs satisfy the following characteristics: SCE1 includes all regions with commercially-viable energy resources; SCE2 includes the commercially-viable regions that are at an average distance of 20 km from the transmission lines; SCE3 includes only the regions at an average distance of 10 km or less from the transmission lines; and SCE4 includes the regions at an average distance of more than 20 km from the transmission lines.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Table 4 shows the installable wind energy capacity (IWEC) in GW, the expected annual energy production (EAEP) in 10^3 GWh/year, and the preventable CO_2 emissions (PCO_2E) in 10^3 Mton/year. The IWEC takes into consideration social, environmental, and techno-economic exclusion zones, for all four scenarios. The EAEP and the PCO_2E are computed based on the IWEC and other technical information obtained during the IWEC analysis. SCE1 gives a maximum estimation of these three indicators, subject to the AZEL assumptions, based on the commercially-viable sites. Here we see that the maximum IWEC is 583.2 GW. Considering that up to December 2018, the IC was 5.14 GW [36,51], we have not even reached 1% of the installable wind energy capacity offered by the land part of the Mexican territory. Indeed, the AZEL data does not include the offshore wind energy potential, which is only available from other publications [24,52].

Table 4. Installable wind energy capacity (IWEC), expected annual energy production (EAEP) and preventable CO_2 emissions (PCO_2E) under the four AZEL scenarios. The information was obtained from the AZEL website (last accessed in 2021).

Indicator	Units	SCE1	SCE2	SCE3	SCE4
IWEC	GW	583.20	290.25	158.30	297.44
EAEP	10^3 GWh/year	1486.71	740.33	402.85	750.19
PCO_2E	10^3 Mton/year	674.97	336.11	182.89	340.58

The AZEL recognizes the crucial importance of access to transmission lines as one of the main limitations of renewable energy developments. Based on proximity to transmission lines alone, the IWEC drops to 290.25 GW, to less than 50% of the total IWEC. This, however, does not provide information on the available voltage of the transmission line, which is also a critical parameter to consider. SCE4 shows the IWEC that could be exploited by isolated turbines connected to a local grid, possibly as a distributed renewable energy system providing energy to the homes and businesses within small human settlements or for agricultural activities. At 297.44 GW of IWEC, this is a very important energy resource. By exploiting this, one could avoid up to 674.97 Mton/year of CO_2 emissions, equivalent to the emissions of almost 70% of the country's population in 2019 [53].

Figure 5 shows the regions included in SCE1, the scenario with all commercially-viable regions. The AZEL has not included, for example, any areas along the Pacific Coast except for the Isthmus of Tehuantepec, and some small regions in the Baja California Peninsula. Therefore, the AZEL is not reporting all the available wind energy resources, as identified with the GWA wind energy resource assessment presented in Section 5. This implies that the AZEL scenarios are underestimating the country's installable capacity, in part due to the limitations of the numerical models on which the scenarios were based. Moreover, the only restriction considered in the AZEL is the site's proximity to transmission lines. Several additional restrictions may be considered, such as land use, exclusions based on topographical characteristics, exposure to natural hazards, AICAs, RAMSAR sites, or others.

Finally, offshore wind capacity has not been considered in the country's future development plans, at least not in the official documents published by the Mexican Ministry of Energy (SENER). However, some studies have attempted to characterize offshore wind energy potential in Mexican waters [24]; the effect of climate change on offshore wind energy resources [52]; and offshore wind energy development under marine planning restrictions in the Gulf of California [23].

7. Long-Distance vs. Distributed Transmission Lines: Challenges and Solutions for Sustainable Growth

Although Mexico has regions with high potential for wind harvesting, the lack of reliable, near-zero leak, high-voltage transmission and distribution lines has been one of the factors hampering the most the growth of this sector [54]. Decisions made in relation to the development of the transmission lines will also determine which regions will implement wind farm developments first. Therefore, it is crucial to plan the national grid's growth adequately. Here we describe the status of the Mexican transmission grid in 2018 and the plans put in place to solve the challenges posed by the grid to renewable energy project developments. It is worth noting that community wind energy project development may also require stronger distributed systems as a solution for the energy transition. We will comment more on this at the end of the section.

The Mexican national transmission network (NTN) consists of four isolated systems: the national interconnected system (SIN); the Baja California Sur (BCS) system; the Baja California (BC) system; and the Mulegé (SEM) system. The SIN is divided further into seven control regions. The BCS, BC, and SEM systems are all located in the Baja California Peninsula; the plan was to connect these three systems to the SIN by 2023 [36]. 94.6% of the gross annual energy consumption (GAEC) in 2017 was concentrated in the SIN, which in that year amounted to a GAEC of 309.73 GW% larger than in 2016, and above the 2007–2017 average annual growth rate of 2.6% [36]. One of the most important limitations for implementing utility-scale renewable energy systems has been transmission line weaknesses [54]. Wind farms are no exception, hence the need to expand and modernize the grid and implement energy storage and smart control systems. For instance, the energy generated in Baja California can only be consumed locally or exported to the United States because none of the transmission line subsystems in the BC peninsula is connected to the SIN.

The federal electricity commission (CFE) currently is the main developer of the NTN. The criteria for NTN developments up to 2018 included the size and location of the energy demand poles, the geographical location of electricity generation plants, and the planned renewable energy farm developments [55]. It is important to highlight that the region with the largest transmission capacity is the Northeastern region, where 25% of the country's capacity is located [55]. This region is connected to the Central region through the states of Queretaro and Veracruz. The interconnection capacity between the central region is also large with the states of Oaxaca and Chiapas. These two states are in the eastern control region. It is believed that the BC subsystem might be able to connect to the SIN by 2023,

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

allowing developments in the BC peninsula to cover part of the demand in the SIN in Northwest Sonora, and vice versa [55].

Figure 6 compares transmission line limits between 2018 and those planned for 2024 by the previous government administration. In some locations, the planned expansions would have doubled the limits. In others, the planned lines consisted of completely new installations, such as the submarine cable connecting the mainland to the middle part of the BC Peninsula, connecting the SIN with the SEM and the BCS grids, the connection of the SIN to the BC system along the Mexico-US border, and the cable connecting Chihuahua and Tamaulipas to the center of the country. These new grid connections would boost the development of renewable energy projects in those regions and provide both energy and employment opportunities. Unfortunately, it is uncertain which grid expansions will go ahead by 2024, mostly for political reasons. An analysis of the new transmission line development plans, published in the latest SENER documents [37], highlighted that the current administration is proposing no substantial advances in maintenance or new developments of the NTN in relation to 2018.

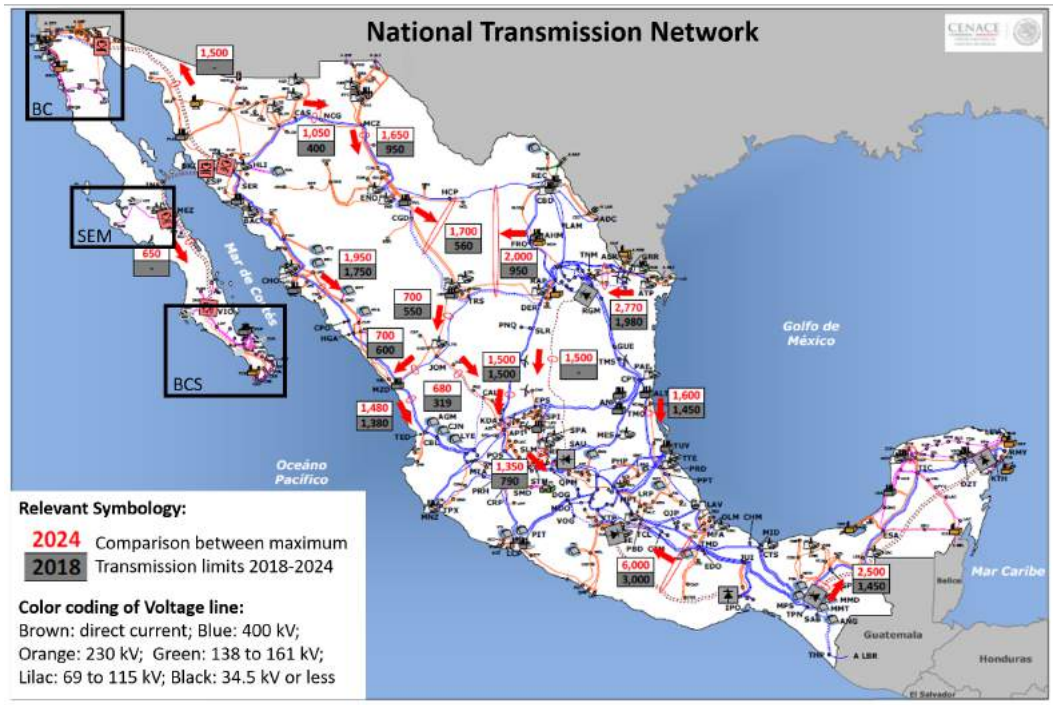

Figure 6. Comparison between the transmission limit for 2018 and that expected in 2024. The NTN consists of four subgrids: the national interconnected system on the mainland; and the Baja California (BC), the Mulegé (SEM), and the Baja California Sur (BCS) grids on the Baja California Peninsula, based on transmission line development plans proposed by the Mexican ministry of energy in 2018 [55].

The current national transmission network (NTN) limitations have important economic consequences. For example, the energy produced in the BC grid can only be consumed locally or exported to the US. Moreover, the Baja California Peninsula is fragmented into three energy islands, the BC, the SEM and the BCS grids. Most lines are 138–161 kV lines, with low transmission limits and high energy losses (see Figure 6). The region with the most transmission capacity is the Northeastern region, with almost 25% of the country's total transmission capacity [55]. The North East is well connected to the central region along the Gulf of Mexico. The states of Oaxaca and Chiapas, on the South, also have high transmission capacity. New NTN developments usually consider the demands for transmission, which depends in turn on the location of current electricity plants and those under planning [55]. CFE historically has been the main developer of the national grid. CFE

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

is not planning new renewable energy projects in the near future, so we can only speculate that CFE will focus on strengthening the existing grid infrastructure, not on installing new grid connections. This means that independent prosumers in isolated regions will need to generate energy, consume it or store it on-site, off the grid.

The weaknesses in the NTN that we have highlighted for the BC Peninsula subgrids and the SIN should be resolved to improve the national connectivity and strengthen the transmission capacity of the whole network. According to the PRODESEN 2018–2032 [36], Mexico needs an additional IC of 67 GW to satisfy the national energy demand between 2018 and 2032, equivalent to an investment of 1.7 billion MXN (almost 50,000 million USD), or 7.8% of Mexico's Gross Domestic Product (GDP) in 2018. Renewable energy projects in isolated regions with high wind speeds will be limited without resolving the grid limitations. Furthermore, we run the risk that all utility-scale wind farm projects are developed in Class I sites already connected to the grid, as has happened in Oaxaca. This is risky, first because the grid will quickly become saturated, and second, because of all the ecological and socio-economical problems that this can generate [56].

A country-wide balanced and equitable development of the wind energy sector should be pursued. Spreading wind farm development throughout the country is feasible because current wind turbines may be installed in locations with different wind classes: Class I, or 10 m/s yearly-averaged wind speeds at hub height; Class II, or 8.5 m/s; Class III, or 7.5 m/s; and Class IV, or 6 m/s, according to the IEC-61400 standards [57]. However, other important parameters may affect wind turbine performance and AEP; and this is reflected in part in the capacity factor of each individual wind farm. Those parameters may include complex topographies or vegetation cover, the turbulent structure at the site, and the effects of wind gusts with return periods of 50 years [57,58], for example. However, as the diversity of the IEC-61400 standard demonstrates, wind turbine technologies are very mature, and therefore several regions in Mexico are good candidates for wind farm developments, even in complex terrain [59].

8. Hydrometeorological Extremes and Their Impacts on Wind Farm Siting

Wind turbines are vulnerable to hydrometeorological extremes, and in most cases, they cannot operate above a cut-off speed of 25 m/s. Any region on the Earth located roughly between the tropics of Capricorn and Cancer (currently the parallels at 23.43655° S and 23.43655° N, respectively) is subject to tropical storms, cyclones and hurricanes. Tropical storms may be defined as mild hydrometeorological perturbations (with wind speeds below 33 m/s or 120 km/h), while tropical cyclones and hurricanes are high wind speed perturbations. Cyclones, like typhoons, are extreme events observed in the Pacific and the Indian Ocean, and hurricanes occur in the Atlantic. Tropical cyclones consist of events where the wind speeds can reach 83 m/s (https://public.wmo.int/es/ciclones-tropicales, accessed on 16 March 2023). Thus, all commercial wind turbines cannot operate even under mild storm conditions. Once the wind speeds reach the turbine cut-off speed, turbine protection mechanisms are activated. In all cases, a lock stops the blades from turning in response to the wind. Some new technologies have been developed that not only stop the blades from turning but lower the whole wind energy conversion system to the ground, like the 30 kW turbine developed and tested at the Regional Centre for Wind Energy Technology site, in Oaxaca [60]; the pilot turbine deployed in 2019 is shown in Figure 7. If the wind speeds are too strong, the turbines are taken down until the extreme conditions end. They are checked for potential damage before being lifted into operational position.

Energy downtime probability plots can be deduced from the turbine specifications and the probability of occurrence of an extreme event.

The vulnerability index due to a tropical storm ($VITS$) is defined as [61]

$$VITS = \sum_{i=1}^{7} I_i \, P(I_i), \tag{1}$$

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

where I_i with $i = 1, 2, \ldots, 7$ is the intensity of the tropical storm, and $P(I_i)$ is the annual probability of exceedance of storms with intensity I_i. I_1 is the intensity of a tropical depression, I_2 the intensity of a tropical storm, and intensities I_3 to I_7 the intensities of hurricanes of categories 1 to 5. The trajectories of the tropical storms between 1949 and 2015 were extracted from the National Hurricane Centre database [62], which have been counted inside and up to 10 km from the border of each of Mexico's counties using the natural (Jenks) break strategy with classes based on hurricane intensity [63,64]. The $VITS$ is then mapped in ways that acknowledge the similarities and differences between regions in terms of their vulnerability to tropical storms. Figure 8 is the $VITS$ computed in [61] for the storms recorded in the period 1949–2015.

Figure 7. 30 kW collapsible turbine trials at the Regional Centre for Wind Energy Technology site in Oaxaca in 2019. Taken from Hernández-Arriaga [60].

Figure 8 illustrates the $VITS$ for all of Mexico, showing regions in Tamaulipas (Tam), the northern part of Veracruz (Ver), Campeche (Cam), Quintana Roo (QR), Jalisco (Jal), Sinaloa (Sin), BC and BCS, with very high $VITS$. Since the $VITS$ is a combination of intensity and probability of exceedance, the regions with high $VITS$ are regions more susceptible to damage by tropical storms. It is also worth noting that the $VITS$ does not consider the population density in the counties mentioned. For instance, BCS has high $VITS$, because, over the hurricane season, the probability is that a hurricane with a category of 3 or above will reach the southern half of the Baja California Peninsula. However, only the southern tip of the Peninsula is highly populated and therefore should be prioritized.

A Risk Index to Tropical Storms (RITS) is defined to correct for population density (D), as mentioned above, and take into consideration a measure of social vulnerability (SV) [65]:

$$RITS = [\ln(D) + 3](SV)(VITS). \quad (2)$$

So, the $RITS$ conditions the vulnerability index by considering the population density and the probability of loss of valuable assets. The value of the assets may be social, economic, or ecological. High $RITS$ regions cover less area than the high $VITS$ regions because the $RITS$ is a $VITS$ with additional restrictions. The $RITS$ is also determined using the method of Jenks natural break strategy [64], a data clustering method that identifies the optimal arrangement for data classification.

As Figure 9 shows, the areas with very high $RITS$ are contained within areas with very high $VITS$ (see Figure 8), as we expected. The areas of high $RITS$ are very well defined. They are located in the southern half of BCS, in some parts of Sinaloa and Jalisco, in southern Tamaulipas and northern Veracruz, and in the Caribbean and the northern parts of the Yucatan Peninsula. The $RITS$ and the $VITS$ complement each other as decision-making tools when it comes to identifying regions that may be better suited for wind farm

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

development. On the one hand, regions with low $VITS$ should be preferred. On the other, if a wind farm is being planned in a high $VITS$ region, it is best to place it in an area of high $RITS$ to minimize construction risks and repair and maintenance costs.

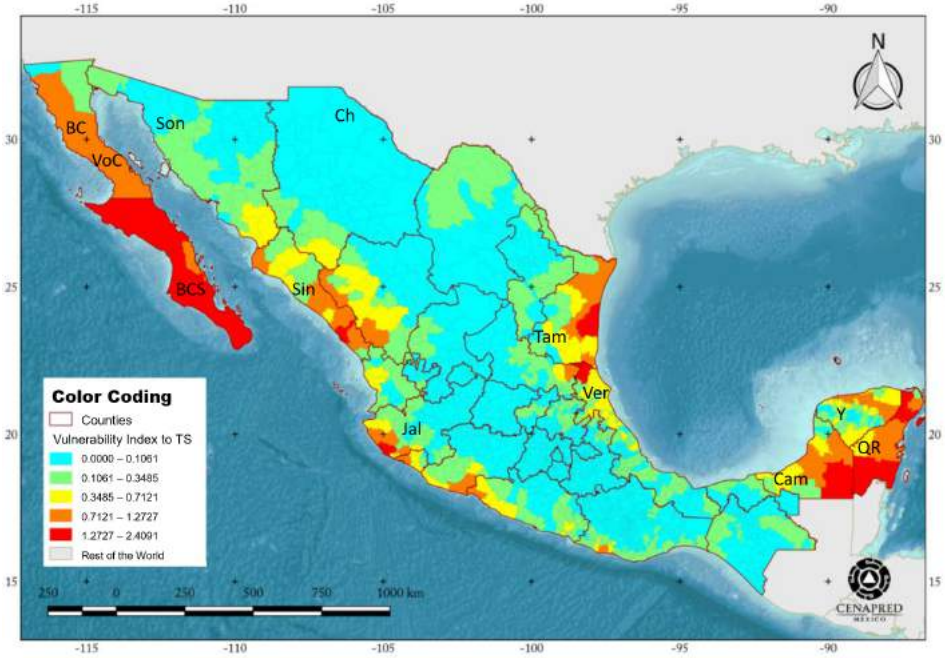

Figure 8. Vulnerability Index to Tropical Storms ($VITS$) based on hurricane trajectories in the period 1949–2015 from the Miami National Weather Centre, National Hurricane Center, and the natural (Jenks) break strategy. QR = Quintana Roo; Y = Yucatán; Cam = Campeche; Ver = Veracruz; Tam = Tamaulipas; Ch = Chihuahua; Son = Sonora; Sin = Sinaloa; BC = Baja California; VoC = Valley of Cirios (see Section 5); BCS = Baja California Sur. Figure reproduced with permission from Baeza-Ramírez and Jiménez-Espinosa [61].

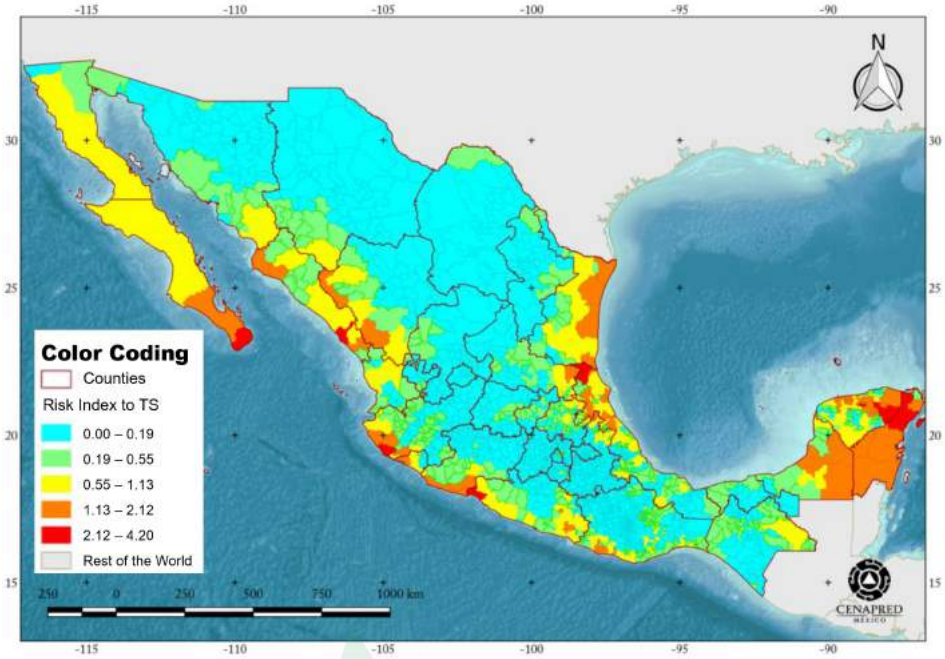

Figure 9. Risk index to tropical storms ($RITS$) for the period 1949–2015. The $RITS$ is defined as the product of the $VITS$ illustrated in Figure 8, by a social vulnerability SV, which is a measure of the value of the assets in the region, and by the factor $\ln(D) + 3$ where D is the population density. Figure reproduced with permission from Baeza-Ramírez and Jiménez-Espinosa [61].

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

In general, the coastal regions are the most vulnerable areas to tropical storms. It is worth noting, in particular, that all the states of QR, the eastern side of Campeche, and the southern half of BCS (see Figure 8) have high to very high *RITS*. Wind energy developments are also most at risk in these regions, especially at the coast and offshore.

9. Long-Term Perspectives

Wind energy development requires improved technical and scientific methodologies, covering aspects of numerical modeling; in situ measurements; technological design, operation and maintenance; and environmental impacts mitigation strategies. Several projects or government programs on modeling and field monitoring campaigns should be planned and implemented to improve wind energy resource evaluations. For example, the sensitivity of the numerical weather forecast predictions to the modeling assumptions, in particular to the coupling with a microscale model as shown in Figure 2, indicates that the bottom boundary data should be improved, including better digital elevation models and better information on vegetation type and land use. Furthermore, while most models assume that the vegetation type does not change, it is a parameter that changes over time. These changes may include deforestation, reforestation, seasonal variations, or urbanization effects on regional wind speeds. Energy resource maps that assess the effects of vegetation and land use changes can allow better planning for urbanization and wind farm development projects. Topography, vegetation and land use resolution on wind energy resources has been recently studied in international projects, such as the "Multi-scale and model-chain Evaluation of Wind Atlases" (MEWA) project [66], the "Innovation for Global Wind Energy Exploitation on Land using Satellites" (InnoWind) project [67], and the "New European Wind Atlas" (NEWA) project [68]. In the future, these studies can be extended to analyze the effects of temporal changes in land use on wind resources.

Studies on the variability and effects of climate change on wind resources at decadal scales are scarce and should be explored more thoroughly. An analysis for Mexico showed the wind energy resources under the RCP8.5 scenario would decrease in Oaxaca [52]. For this reason, it is necessary to continue implementing numerical models that assess the effects of climate change, in particular for the RCP8.5 scenario. The IPCC recommendations imply that this is the scenario we must consider when evaluating impacts since only then will we provide information that is more appropriate to the reality of the climate crisis and its possible effects.

It is also imperative to continue measuring atmospheric variables with sensors at hub height, such as those carried out in the MWA project led by the National Institute of Electricity and Clean Energies [50]. In the MWA, ten monitoring towers were installed throughout the country. These measurements allow the study of local wind conditions and provide a reference for evaluating numerical models. These models help plan the wind farm layout, including the number of turbines and their geographical locations, to maximize energy production and minimize environmental impacts. More extensive project planning exercises also need to assess wind farms' interactions, since one plant may affect the flow field reaching the plants located downstream.

Despite being a mature technology with significant progress in its implementation at the commercial level, the dismantling and recycling of wind conversion systems, or at least of the parts, continues to be a big problem [69]. One reason is that few commercial wind plants are reaching the end of their life, and therefore there is little experience in decommissioning and recycling wind turbine parts. The other is that many plants that have already completed their life cycle continue to generate electricity. However, the recycling problem is beginning to be addressed, both by academia and industry. The blades are the part of the turbine that has received the most attention, although some manufacturers, including Vestas [70], have addressed the complete turbine's recycling problem. The magnitude of the recycling problem will depend mainly on the IC 30 to 40 years from now. The growth of IC depends, in turn, on the wind energy growth roadmap. The Organization

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

for Economic Cooperation and Development and the International Energy Agency, for example, consider two possible growth scenarios [71]: the "2DC" scenario (2 °C)—with a Global IC of 1400 GW by 2030 and of 2300 GW by 2050; and the "HiRen" scenario (Renewables)—with a Global IC of 1600 GW by 2030 and of 2700 GW by 2050.

Life cycle analyses must consider the growth roadmaps to 2030 and 2050 to properly assess the type and volume of materials that need to be mined or manufactured. Recycling and reusing processes will help minimize waste during the decommissioning stage. The growth roadmaps are also critical when evaluating potential environmental impacts. Dismantling, recycling, or waste disposal must take into account some of the following, among other possible factors:

1. 5% of the IC installed by 2030 will need to be dismantled by 2050 [72].
2. Turbine size will change. Currently, turbines have, on average, 2 MW of IC, but the capacity is expected to increase to 10 MW by 2030 [73].
3. Changes in design and construction materials. For example, steel is easily recyclable, but it is challenging to handle and recycle fiberglass.
4. Take into account submarine cabling in the case of offshore wind farms [74].
5. Uncertainties and limitations in recovering and processing materials from offshore wind farms.
6. Type of vegetation and changes in land use should be included in the environmental impact studies, and the measures to reduce or correct these impacts should be accounted for in the budget [75].

Finally, it is essential to highlight that, to meet the sector's needs, it will be necessary to train thousands of specialists from different disciplines who focus only on the wind sector to achieve substantial advancements in research and technological development. The number of engineers and scientists explicitly training to become renewable energy professionals is extensive. However, this training is usually very general, limiting specific and highly advanced skill development in each renewable energy specialization sector that we must promote nationally.

10. Conclusions

A review of wind energy development in Mexico, focusing on the factors hampering it and on proposals for solutions, is presented. This analysis is relevant in the context of climate change mitigation strategies and the achievement of the UN's sustainable development goals. Indeed, wind and solar are currently the two most mature and easily scalable renewable energy technologies.

An analysis of the global and Mexico's installed capacity and wind generation for the past ten years shows that wind growth has reduced significantly since 2020 in Mexico. New government policies favoring fossil fuels over renewable energies are partially responsible for this growth deceleration. However, investments in renewable energies are essential to economic growth compatible with sustainable development goals.

Although the wind energy private sector in Mexico has been criticized for socially unfair land lease agreements with the land owners and for not addressing local energy poverty problems, community wind energy projects have shown that privately-owned projects, when led by local communities, can address energy poverty and achieve sustainable development goals. However, all energy projects would be more successful in attaining a return on investment and would do so faster if feasibility studies and environmental impact assessments were more robust. For example, most wind atlases are not precise enough, in part because they do not couple microscale and mesoscale models in their analysis. Indeed, the relative differences in wind power density estimates between mesoscale and micro-mesoscale models can be as large as 50% in some locations, demonstrating the importance of considering the microscale effects on wind energy characterization.

Four wind generation scenarios were examined. However, these scenarios only consider the regions with the highest annual wind power densities. Therefore, the installable wind energy capacity and the expected annual energy production may be significantly

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

underestimated. Moreover, none of these scenarios takes into consideration Mexico's territorial waters. Proximity to high-voltage transmission lines is recognized as one of the most important limiting factors for renewable energy development. Thus, we analyze the Mexican NTN and its status in 2018, together with the development plans envisioned by the Mexican Ministry of Energy by 2024. However, the vision changed significantly during the current administration, and the weaknesses observed in the 2018 NTN are unlikely to be addressed in the near future, except for the high-voltage interconnection between the BC and the SIN grid networks, thanks to a solar energy megaproject currently being developed in Sonora.

Another crucial limitation of wind energy generation is the vulnerability and risk to extreme events. Because tropical storms are common in most of Mexico, we analyze the maps of vulnerability and risk index to tropical storms. Other vulnerability and risk index maps for other extreme events, such as snow storms, would be important at other latitudes and higher altitudes. Novel technology concepts are currently being proposed, built and tested to mitigate against damage by extreme events and low energy generation.

Improving micro-mesoscale models, providing in situ data for weather monitoring, and integrating models and in situ data with remotely sensed information, are discussed in long-term perspectives. Machine Learning methods combined with mesoscale models may help improve model performance and reduce computational costs. Decadal scale studies assessing climate change effects on wind speeds, wind power density atlases, and vulnerability and risk indexes are required. Furthermore, better generation scenarios would lead to better planning. Combining these scenarios with growth roadmaps would be critical for cost−benefit analyses, for more accurate estimates of carbon emission reductions, and potential environmental impacts, especially as turbines grow and decommissioning and material recycling practices improve. Finally, the need for a highly skilled workforce cannot be understated, with the industry growing faster than the number of specialized staff.

Alarm Krisis Iklim Makin Kencang, Transisi Energi Mendesak Dilakukan Halaman all - Kompas.com

Hilda B Alexander

JAKARTA, KOMPAS.com - Intergovernmental Panel on Climate Change (IPCC), badan PBB yang bertanggung jawab untuk sains iklim, sekali lagi menggemakan alarm peringatan tentang dampak iklim yang semakin cepat dan keras.

Dalam Sintesa Laporan Penilaian keenam (AR6), negara-negara berkembang diprediksi akan merasakan dampaknya terlebih dahulu, meskipun akhirnya memengaruhi semua bentuk kehidupan di Bumi.

Laporan tersebut menyarankan pengurangan emisi yang cepat dan signifikan pada sumbernya, karena dengan infrastruktur bahan bakar fosil yang sudah ada saat ini, akan membuat batas kenaikan temperatur 1,5°C terlampaui.

Namun, Deputi Eksternal Walhi Ode Rakhman menilai, keputusan yang dibuat saat ini sangat bergantung pada solusi-solusi palsu, berbahaya, dan berisiko.

"Alih-alih transformasi mendalam dan sistemik yang benar-benar dibutuhkan," ujar Ode, dikutip dari laman Walhi, Kamis (23/3/2023).

Baca juga: Terancam Krisis Iklim, Indonesia Harus Percepat Transisi Energi

Meskipun AR6 dengan jelas menyatakan bahwa hanya melalui pengurangan emisi gas rumah kaca (GRK) yang ekstensif, cepat dan berkelanjutan, pemanasan global akan teratasi, tapi terdapat opsi-opsi lain yang bisa diambil.

Terutama dari teknologi penghapusan karbondioksida (*carbon diaoxide removal*), hydrogen, amonia, biofuel dan gas fosil yang dimasukkan dalam bagian dari “berbagai peluang untuk meningkatkan aksi iklim”.

Menurut Ode, pendekatan solusi palsu dalam upaya mengatasi perubahan iklim yang ditampilkan secara sentral dalam Laporan IPCC ini tentu mengkhawatirkan.

Hal ini karena AR6 akan menjadi pembenaran bagi banyak negara untuk menghindari upaya yang lebih sistematis dan ambisius dalam menekan emisi GRK, dan justru semakin jauh mengadopsi solusi-solusi palsu.

Contohnya yang dilakukan Pemerintah Indonesia, yang dalam berbagai kesempatan menyebut peta jalanan transisi energi akan menggunakan produk-produk hilirisasi batu bara, hidrogen, fosil gas, biofuel dan berbagai macam pendekatan *co-firing* PLTU.

Ode menilai pilihan ini akan semakin menjauhkan Indonesia dari upaya untuk menekan emisi GRK, dan justru bisa menghasilkan kerusakan lingkungan yang lebih parah, serta melakukan berbagai pelanggaran HAM dalam praktiknya.

"Pilihan jalan ini pada akhirnya akan lebih mengakomodasi kepentingan oligarki industri fosil dan kelompok pencemar besar yang ingin terus mengekstraksi dan membakar setiap gram batu bara, minyak dan gas terakhir," cetus Ode.

Untuk itu, Ode mengatakan, Indonesia membutuhkan transisi yang mendesak, adil dan merata menuju energi terbarukan untuk semua.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

...donesia harus mengindahkan pesan mendesak dalam laporan IPCC, tanpa jatuh ke dalam perangkap asumsi bahwa proyek-proyek dan teknologi-teknologi solusi palsu akan membawa perbaikan dari ancaman krisis iklim.

"Proyek-proyek semacam ini justru akan menyebabkan lebih banyak kerusakan lingkungan, perampasan tanah dan pelanggaran hak, terutama pada kelompok rentan, dan justru memperburuk krisis iklim, alih-alih menyelesaikannya," tuntasnya.

Apa Saja Sumber Energi Terbarukan yang Ada di Indonesia? Halaman all - Kompas.com

Lulu Lukyani

KOMPAS.com - Sejak tahun 1950, permintaan energi global telah meningkat tiga kali lipat dengan pemakaian yang diperkirakan telah mencapai 10.000 juta ton per tahun.

Sebagian besar energi yang saat ini digunakan berasa dari bahan-bahan yang tidak terbarukan, seperti batubara, gas, minyak bumi, dan energi nuklir.

Jika terus-menerus digunakan, sumber-sumber energi yang tidak terbarukan ini dapat habis. Dengan demikian, menggunakan energi terbarukan sebagai alternatifnya adalah langkah yang penting.

Sumber energi terbarukan di Indonesia

Dilansir dari Pusat Studi Energi, Universitas Gadjah Mada (UGM), energi terbarukan adalah energi yang berasal dari sumber-sumber alamiah, seperti sinar matahari, angin, hujan, geothermal dan biomassa.

Beberapa sumber energi terbarukan *(Renewable Energy Resources)* yang potensial dan berlimpah di Indonesia adalah angin, geothermal, hydropower, surya, biomassa (biogas, biofuel padat dan biofuel cair).

Baca juga: YLKI: Subsidi Energi Perlu Memprioritaskan Energi Baru dan Terbarukan

1. Angin

Angin adalah sumber energi terbarukan yang paling berlimpah di dunia.

Menurut Ditjen Listrik dan Pemanfaatan Energi (2009), potensi energi angin sebagai energi terbarukan di Indonesia mencapai 9290 MW.

2. Geothermal

Geothermal atau panas bumi adalah energi terbarukan yang diperoleh dari panas bumi.

Saat ini, di dunia, termasuk Indonesia, energi geothermal termasuk energi yang menjanjikan dari seluruh RES yang ada.

Data Ditjen Listrik dan Pemanfaatan Energi (2009) menunjukkan bahwa potensi geothermal Indonesia mencapai 27.000 MW.

Baca juga: DMO Batu Bara Disebut Tak Seharusnya Masuk dalam RUU Energi Baru Terbarukan

Mengutip laman Himpunan Mahasiswa Teknik Perminyakan, Institut Teknologi Bandung (ITB), energi geothermal merupakan salah satu energi alternatif yang potensial dikembangkan di Indonesia karena faktor letak geografis Indonesia yang berada pada ring of fire.

Indonesia diimpit oleh tiga lempeng tektonik, yaitu lempeng eurasia, lempeng indo-asutralia, dan lempeng pasifik.

Aktifitas tektonik ini mengakibatkan terbentuknya zona subduksi dibawah Pulau Sumatera, Jawa, Bali, Nusa Tenggara, dan Sulawesi sehingga menciptakan sumber panas berupa magma yang merupakan cikal bakal gunung berapi.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Air

Sumber energi terbarukan air antara lain berupa aliran sungai, air terjun dan pasang surut air laut.

Air merupakan RES yang sangat melimpah di Indonesia. Menurut Ditjen Listrik dan Pemanfaatan Energi (2009), potensi Hydropower Indonesia mencapai 4,99 x 1018 J/tahun.

Baca juga: Isu Transisi Energi Dibahas dalam Presidensi G20, Ini Hal yang Perlu Diprioritaskan Pemerintah

4. Energi surya

Energi surya adalah energi terbarukan yang dihasilkan dari matahari dalam bentuk radiasi matahari.

Energi terbarukan seperti energi surya cocok dikembangkan di wilayah Nusa Tenggara karena intensitas matahari terbaik di Indonesia berada di Pulau Sumba dan Timor, sebagimana dikutip dari Kompas.com (27/09/2020).

5. Biomassa

Energi alternatif dari biomassa adalah salah satu bentuk energi yang populer dalam penggunaan energi terbarukan.

Bioenergi pada dasarnya adalah energi yang dihasilkan dari biomassa.

Sumber energi yang termasuk bioenergi antara lain biogas, biofuel cair dan biofuel padat.

Baca juga: Bagaimana Proses Perubahan Energi yang Terjadi pada PLTA?

Energi biomassa lebih potensial dikembangkan di wilayah pedesaan. Hal ini karena kayu, daun, sekam padi, dan jerami (sumber biomassa) merupakan bahan bakar utama untuk pemanasan dan memasak di wilayah pedesaan.

Catatan dari International Energy Agency menunjukkan, energi biomassa menyediakan 30 persen dari suplai energi utama di beberapa negara berkembang.

BRIN Kaji Kesiapan Energi Terbarukan dan Nuklir

BRIN Kaji Kesiapan Energi Terbarukan dan Nuklir

BRIN Kaji Kesiapan Energi Terbarukan dan Nuklir

Diterbitkan pada 24 Oktober 2022

Jakarta-Humas BRIN. Kedeputian Bidang Kebijakan Pembangunan (DKP) BRIN kembali mengadakan Bincang Pembangunan. Acara yang dihelat di Auditorium BRIN Gatot Subroto Senin (24/10) ini mengusung tema "Kesiapan Energi Terbarukan dan Nuklir dalam Mendukung Pencapaian *Net-Zero Emission*". Deputi Bidang Kebijakan Pembangunan BRIN, Dr. Mego Pinandito menyampaikan bahwa Bincang Pembangunan kali ini bertujuan untuk melakukan diskusi dengan pakar yang berkaitan kesiapan dan pemanfaatan potensi energi terbarukan dan nuklir dalam mendukung pembangunan dan memajukan bangsa. "Diskusi ini juga mencari langkah dan strategi yang tepat dalam memanfaatkan energi terbarukan dan nuklir untuk mendukung pencapaian *net-zero emission* yang dapat menunjang dan berperan dalam pembangunan nasional," tegasnya.

Secara garis besar, DKP menginisiasi Seri Bincang Pembangunan untuk mendapatkan pengetahuan dan wawasan baru dalam konteks kebijakan strategis terkait isu-isu saat ini. Tema yang diangkat kali ini didasarkan pada upaya atau komitmen Indonesia untuk menangani isu perubahan iklim. Indonesia telah meratifikasi Paris Agreement melalui UU No. 16 Tahun 2016, yang artinya Indonesia ikut serta untuk menahan kenaikan suhu global sebesar 2^{0}C dan berupaya lebih jauh untuk membatasinya hingga 1,5^{0}C di atas era pra-industri. Dalam dokumen Enhanced Nationally Determined Contribution (ENDC), Indonesia menargetkan penurunan emisi Gas Rumah Kaca (GRK) sebesar 31,89%, dengan upaya sendiri hingga 43,20% dengan bantuan internasional pada tahun 2030. Selain itu, pada Conference of the Parties ke-26 (COP-26), Indonesia menargetkan pencapaian Net-Zero Emission (NZE) pada tahun 2060 atau lebih cepat.

...or energi merupakan salah satu sektor penyumbang emisi GRK terbesar di Indonesia. Kontribu...

sebut disebabkan oleh tingginya penggunaan energi fosil terutama pada aktivitas produksi listr dan panas, transportasi, serta industri manufaktur dan kegiatan konstruksi. Transisi energi dengan beralih dari penggunaan energi fosil menuju energi baru terbarukan dapat menjadi solusi untuk mengurangi tingkat emisi tersebut.

Indonesia memiliki potensi energi baru terbarukan berupa panas bumi, surya, angin, air, bioenergi, arus laut, dan nuklir yang pada tahun 2021 hanya berkontribusi pada 12,16% bauran energi nasional. Untuk mencapai target-target iklim di atas, maka perlu upaya percepatan transisi energi. Mego juga menyampaikan faktor penentu keberhasilan transisi energi untuk mendukung pencapaian NZE, diantaranya: Kebijakan dan Regulasi, Teknologi, Investasi dan Insentif, serta Kolaborasi.

Melalui Bincang Pembangunan Seri VIII ini, Mego berharap para peserta mendapatkan *insight* dari para pakar melalui diskusi, pertukaran informasi dan gagasan terkait kesiapan energi terbarukan dan nuklir dari perspektif kebijakan dan regulasi, riset-inovasi teknologi, dan tren di negara-negara ASEAN. “Kami mengharapkan perolehan masukan dan pemikiran untuk penyusunan rekomendasi kebijakan pada sektor energi nasional, khususnya terkait pengembangan energi terbarukan dan nuklir dalam mendukung pencapaian NZE,” tutupnya.

Acara kali ini dibagi dalam dua sesi, sesi pertama membahas Kebijakan, Regulasi, dan Proyeksi Transisi Energi lalu pada sesi kedua berfokus pada Kebijakan, Regulasi, dan Proyeksi Transisi Energi. Hadir perwakilan dari Kementerian Energi dan Sumber Daya Mineral (ESDM), Dewan Energi Nasional, ASEAN Centre of Energy, Dewan Pakar Masyarakat Energi Terbarukan Indonesia, Perekayasa dan Pengembang Nuklir BRIN. Diskusi ini dapat disaksikan pada kanal YouTube BRIN Indonesia. (sgd)

Butuh Upaya Out of The Box Capai Target Bauran EBT

Liputan6.com

Sebelumnya, Pemerintah gencar mendorong pemanfaatan Pembangkit Listrik Tenaga Surya (PLTS) Atap untuk memenuhi kebutuhan energi listrik pada berbagai sektor.

Target capaian nol emisi karbon pada tahun 2060 serta tingkat bauran energi terbarukan sebesar 23 persen di tahun 2025 dapat diraih dengan pengembangan energi surya secara masif, khususnya pada sektor industri komersial. Sektor industri dipercaya menjadi sektor potensial untuk percepatan penetrasi energi baru terbarukan (EBT).

Sejalan dengan upaya pemerintah untuk meningkatkan angka bauran energi terbarukan, SUNterra giat bekerja sama dengan berbagai pihak untuk melakukan instalasi Pembangkit Listrik Tenaga Surya (PLTS) guna mengurangi jejak karbon dari aktivitas operasional setiap perusahaan.

Berfokus pada sektor residensial, sosial, dan komersial skala menengah, SUNterra berhasil mencatat proyek PLTS lebih dari 2,5 MWp semenjak didirikan pada tahun 2020.

PT Modern Plastic Industry (MPI) merupakan salah satu portofolio komersial yang membanggakan bagi SUNterra. Perusahaan yang bergerak sebagai produsen kemasan plastik ini mulai menjalankan praktik bisnis yang berkelanjutan dengan instalasi PLTS Atap berkapasitas 151,25 kWp.

Instalasi sistem PLTS pada PT MPI menggunakan sistem On Grid yang masih terhubung dengan jaringan PLN dengan kapasitas per panel sebesar 550 Wp.

“Tidak hanya operasional pabrik saja, instalasi PLTS dengan kapasitas 151,25 kWp ini juga menyumbang pasokan energi pada kegiatan perkantoran yang berada pada lokasi yang sama. Pada awal tahun 2023, masih bersama dengan SUNterra, kami juga berencana menambah kapasitas PLTS sebesar 201 kWp, sehingga total PLTS di green energy factory kami menjadi 352 kWp,"
kata Perwakilan PT MPI Michael Jusanti, Rabu (11/1/2023).

SUNterra menggunakan panel surya dari Jinko Solar sebanyak 275 unit, yang dilengkapi dengan MBB HC Technology, membuat setiap panel yang terpasang di PT MPI ini memiliki durabilitas dan performa sistem PLTS yang tangguh.

Catatan Akhir Tahun: Melihat Capaian Energi Terbarukan 2022, Bagaimana Peluang Tahun Depan?

oleh Della Syahni [Banten] di 29 December 2022

- *Sampai penghujung tahun ini terlihat pangsa energi terbarukan (https://iesr.or.id/pustaka/indonesia-energy-transition-outlook-ieto-2023) dalam bauran energi primer Indonesia turun dari 11,5% pada 2021 jadi 10,4% pada 2022. Kondisi ini karena pangsa batubara meningkat 43%.*
- *Kenaikan pangsa batubara ini bisa membuat target 23% pengembangan energi terbarukan pada 2025 sulit diraih kalau pemerintah tak segera memperkuat komitmen politik terhadap pengembangan energi terbarukan.*
- *Fabby Tumiwa, Direktur Eksekutif IESR mengatakan, meski ada komitmen mengakselerasi pemanfaatan energi terbarukan, masih ada perbedaan persepsi dan prioritas berbagai pembuat kebijakan tentang bagaimana proses transisi dilakukan.*
- *Indonesia Energy Transition Outlook 2023 (https://iesr.or.id/pustaka/indonesia-energy-transition-outlook-ieto-2023) memperlihatkan kalau kesadaran masyarakat tinggi terhadap transisi energi. Namun, beberapa hal harus dibenahi seperti pembatasan kapasitas pada pemasangan PLTS atap 15%, yang menurunkan minat masyarakat memanfaatkan teknologi ini. Kondisi ini, berkontribusi pada bauran energi terbarukan dalam skala nasional.*

Tahun 2022 segera berganti. Bagaimana kondisi transisi energi di Indonesia? Dari pengukuran kesiapan bertransisi (*transition readiness framework*) memperlihatkan, kesiapan Indonesia bertransisi energi masih rendah meskipun beberapa kebijakan, dan rencana pengembangan energi

erbarukan sudah terbit. Itu antara lain tercantum dalam laporan *Indonesia Energy Transition Outlook (IETO) 2023 y (https://iesr.or.id/pustaka /indonesia-energy-transition-outlook-ieto-2023)*ang dirilis Institute for Essential Services Reform (IESR) atas dukungan Bloomberg Philanthropies ini.

Beberapa kebijakan yang mendukung pengembangan energi terbarukan seperti, seperti *enhanced nationally determined contributions* (NDC), rencana umum pengembangan tenaga listrik (RUPTL) 2021-2030 dengan porsi 51,6 % energi terbarukan. Juga, sudah ada Perpres 112/2022 mengenai percepatan pengembangan energi terbarukan untuk penyediaan tenaga listrik.

Laporan IETO menemukan, pangsa energi terbarukan dalam bauran energi primer Indonesia menurun dari 11,5% pada 2021 jadi 10,4% pada 2022. Kondisi ini karena pangsa batubara meningkat 43%, membuat target 23% pada 2025 akan sulit diraih kalau pemerintah tak segera memperkuat komitmen politik terhadap pengembangan energi terbarukan.

"Ada perbedaan kontras antara ambisi dan realisasi perkembangan energi terbarukan," kata Fabby Tumiwa, Direktur Eksekutif IESR saat peluncuran IETO di Jakarta, baru-baru ini.

Meski ada komitmen mengakselerasi pemanfaatan energi terbarukan, katanya, masih ada perbedaan persepsi dan prioritas berbagai pembuat kebijakan tentang bagaimana proses transisi dilakukan.

Kondisi ini, katanya, terlihat pada keputusan meniadakan *feed in tariff* pada Perpres 112/2022 dan penolakan terhadap klausula *power wheeling* (pemanfaatan bersama jaringan tenaga listrik termasuk untuk energi terbarukan) pada perumusan Rancangan Undang-undang Energi Baru dan Terbarukan (RUU-EBT). Juga, keputusan mempertahankan subsidi batubara dalam bentuk harga *domestic market obligation* (DMO).

Untuk transisi energi efektif, katanya, pemerintah harus punya kesatuan posisi dan menetapkan target.

IETO 2023 juga menyoroti pencapaian investasi energi terbarukan yang masih kurang dari target pemerintah, hanya US$1,35 miliar sampai kuartal ketiga 2022 alias hanya 35% dari target 2022 sebesar US$3,97 miliar.

Menurut IESR, iklim investasi perlu diperbaiki dengan memperbanyak dukungan finansial untuk pengembang energi terbarukan, proses pengadaan, skema tarif, dan proses perizinan lebih singkat dan jelas.

Pemerintah, katanya, juga perlu mengurangi hambatan masuk investor asing, dan meningkatkan akses ke modal dengan suku bunga yang lebih rendah.

"Selain itu, penyediaan ruang lebih luas bagi integrasi energi terbarukan dalam sistem energi Indonesia harus segera dilakukan," kata Fabby.

Hal yang dapat dilakukan untuk memberikan ruang bagi penetrasi energi terbarukan, selain dari melakukan pensiun dini PLTU, adalah mengoperasikan PLTU secara fleksibel.

Secara teknis, pengoperasian ini akan perlu perubahan dalam komponen-komponen utama PLTU dan fleksibilitas dalam perjanjian jual beli listrik serta kontrak suplai bahan bakar.

Baca juga: Transisi Energi ala Campur Batubara dan Biomassa Hadapi Kendala (https://www.mongabay.co.id/2022/09/29/transisi-energi- campur-batubara-dan-biomassa-hadapi-kendala/)

Tongkang batubara di sungai Mahakam di Samarinda, Kalimantan Timur. Foto : Kemal Jufri/Greenpeace.

Antisipasi krisis energi

Krisis energi global menunjukkan, kerentanan ketahanan energi berbasis fosil, termasuk Indonesia, masih 67% energi fosil.

Guna menghadapi ketidakpastian situasi sosial, politik, ekonomi dan lingkungan masa depan terhadap ketahanan energi nasional, katanya, pemerintah perlu cepat dan segera transisi energi berkeadilan dan berkelanjutan. Tentunya, dengan optimasi pemanfaatan sumber energi terbarukan dan gantikan energi fosil.

Hal ini jadi sorotan dalam IETO 2023 adalah dampak krisis energi terlihat pada harga batubara, gas alam, dan minyak mentah melambung 2-4 kali pada pertengahan 2022 dibandingkan pada 2019.

Buntutnya, produsen batubara domestik lebih tertarik mengekspor, menyebabkan pasokan batubara dalam negeri menipis. Untuk mengatasi masalah krisis energi jangka pendek, katanya, pemerintah Indonesia membuat berbagai keputusan seperti mempertahankan kebijakan DMO, mengucurkan subsidi energi fosil mencapai Rp650 triliun dan menyesuaikan harga BBM untuk mengurangi beban subsidi.

Menurut Fabby, kondisi negara-negara Eropa dan Inggris yang mengalami harga energi mahal adalah contoh pemanfaatan *transition fuel* seperti gas alam sebagai strategi keliru.

Ketika terjadi kekurangan gas, katanya, mereka secara temporer menaikkan energi fosil. Kondisi ini justru mengingkari upaya global dalam menekan emisi gas rumah kaca (GRK) yang menyebabkan perubahan iklim.

Untuk itu, IESR mendorong pemerintah membereskan seluruh pekerjaan rumah dalam menggenjot perkembangan energi terbarukan dan efisiensi energi dengan cepat. Yakni, dengan menyesuaikan kebijakan energi nasional dan RUEN, penghapusan subsidi batubara dan gas secara bertahap. Juga, reformasi harga dan subsidi listrik, mempercepat pengakhiran operasi PLTU

PERPUSTAKAAN NASIONAL

batubara, mengembangkan industri sel dan modul surya dalam negeri.

Kemudian, katanya, penyesuaian aturan jaringan sistem tenaga listrik (*grid code)*, dan mengintegrasikan strategi transportasi maupun dekarbonisasi industri sesuai jalur nir emisi.

""Kata kuncinya, target ambisius juga fleksibel. Pemerintah harus mengejar semua reformasi ini secara cepat dan masyarakat harus terus mendorong agar transisi benar-benar terjadi."

Sisi lain, sektor transportasi dan industri jadi krusial untuk dekarbonisasi dengan cepat.

Pada sektor transportasi, ada tren menarik pada adopsi kendaraan listrik yang meningkat. Terlihat dari jumlah kendaraan roda dua dan tiga yang naik hampir lima kali lipat dari 5.748 pada 2021 jadi 25.782 pada 2022.

Meskipun demikian, jumlah ini masih jauh dari target NDCs yang menetapkan 13 juta kendaraan roda dua dan tiga pada 2030.

"Pemerintah perlu mendorong penciptaan ekosistem transisi energi di semua sektor energi, salah satunya, menciptakan level *playing field* antara energi fosil dan alternatif teknologi rendah karbon dan energi terbarukan," kata Deon Arinaldo, Manajer Program Transformasi Energi, IESR.

Langkah awal yang perlu dikaji, katanya, bagaimana subsidi dan kompensasi energi saat ini bisa teralih untuk pemberian insentif pengembangan energi terbarukan dan adopsi teknologi rendah karbon. Juga saat bersamaan tetap membantu menjaga kesejahteraan masyarakat.

Baca juga: Kajian Ini Ungkap Energi Bersih Lebih Hemat daripada PLTU (https://www.mongabay.co.id/2019/12/02/kajian-ini-ungkap-energi-bersih-lebih-hemat-daripada-pltu/)

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

Sektor industri

Penggunaan energi fosil industri menyumbang sekitar 20% emisi gas rumah

...ca (GRK) sektor energi Indonesia. Peningkatan efisiensi proses dan efisiensi energi serta penggantian bahan bakar telah diterapkan oleh beberapa industri intensif energi untuk mengurangi emisinya.

Raditya Wiranegara, peneliti senior IESR juga penulis IETO 2023 mengatakan, implementasi *carbon capture, utilization and storage* (CCUS) dapat jadi strategi jangka pendek dalam mengurangi emisi proses pada industri semen, pupuk, dan baja. Upaya-upaya ini, katanya, belum dimulai. Industri, katanya, perlu pula mengembangkan teknologi rendah karbon alternatif, seperti amonia berbasis elektrolisis untuk pupuk dan proses peleburan besi (*direct reduction iron-electric arc furnace*/DRI-EAF) berbasis hidrogen.

"Saat ini, pengembangan teknologi rendah karbon sektor industri sebagian besar masih tahap awal kesepakatan studi bersama," kata Raditya.

IESR pun mendorong pemerintah mencapai bauran energi terbarukan 100% dalam bauran energi primer pada 2050 dan bauran energi terbarukan lebih 40% di sektor ketenagalistrikan pada 2030.

"Apabila pemerintah dapat memanfaatkan peluang dan dukungan itu maka daya tarik dan bauran energi terbarukan pasti akan meningkat," katanya.

Energi surya atap yang dikembangkan masyarakat. Minat masyarakat tinggi terhadap surya atap, Foto: Sapariah Saturi/ Mongabay Indonesia

Partisipasi masyarakat

IETO 2023 juga memperlihatkan kalau kesadaran masyarakat tinggi terhadap transisi energi. Namun, katanya, beberapa hal harus dibenahi seperti pembatasan kapasitas pada pemasangan PLTS atap 15%, yang menurunkan minat masyarakat memanfaatkan teknologi ini. Kondisi ini, berkontribusi pada bauran energi terbarukan dalam skala nasional.

"Berdasarkan survei publik, lebih 60% masyarakat yang kami survei setuju mempercepat pemberhentian penggunaan batubara sebagai sumber utama ...m sektor ketenagalistrikan dan mendukung pemerintah mulai

PERPUSTAKAAN NASIONAL

memperhatikan sumber-sumber lain seperti radiasi matahari, air, dan angin," kata Handriyanti D Puspitarini, peneliti senior IESR dan penulis utama IETO 2023.

Dengan dukungan publik besar itu, katanya, pemerintah harus mulai bisa membuktikan komitmen dalam menyediakan sumber listrik lebih bersih untuk seluruh masyarakat.

Menanggapi kajian ini, Harris, Direktur Panas Bumi Kementerian Energi dan Sumber Daya Mineral (KESDM) benarkan pencapaian bauran energi terbarukan belum persis seperti target tahunan. Pada 2021, target 14,5% pada 2023 sesuai RUEN, baru tercapai 12,2%.

"Itu baru persentase. Jika dilihat volume megawatt-nya lebih *ga match* lagi karena ada perubahan drastis," kata Harris. Meski demikian, bauran energi terbarukan tetap naik meski sedikit.

Mengenai usulan menaikkan target lebih ambisius, kata Harris, sebaiknya Indonesia memastikan dulu target 51% dalam RUPTL saat ini bisa tercapai mengingat pengalaman sebelumnya jarang penuhi target.

"Kita sudah puya regulasi, meski belum sempurna," katanya.

Harris juga melihat prioritas yang disoroti dalam IETO 2023 agak berbeda dengan prioritas KESDM. IETO begitu optimis menggenjot PLTS, yang menurut dia perlu dipertimbangkan skenario mencapai target 1.400 gigawatt.

"Kita masih punya yang lain seperti panas bumi, hidro, dan lain-lain."

Dia usulkan, lebih banyak pembahasan mengenai energi efisiensi sebagai satu langkah dekarbonisasi yang jarang mendapat sorotan dalam kajian.

China akan Luncurkan Skema Percontohan Perdesaan untuk Energi Terbarukan

Supianto | Jum'at, 24/03/2023 01:01 WIB

Turbin angin berdiri di pembangkit listrik dekat Yumen, provinsi Gansu, Cina 25 September 2020. REUTERS/Carlos Garcia Rawlins/File Foto

JAKARTA, Jurnas.com - China akan meluncurkan skema percontohan untuk mempromosikan pengembangan energi terbarukan di daerah pedesaan. Demikian menurut rencana aksi yang dirilis oleh Administrasi Energi Nasional (NEA) pada Kamis (23/4).

Di bawah skema tersebut, departemen pemerintah tingkat provinsi akan mengidentifikasi `daerah percontohan` perdesaan untuk pembangunan proyek energi terbarukan dan menyerahkan rencana pengembangan ke NEA untuk dievaluasi dan disetujui pada akhir Mei tahun ini.

Skema tersebut mengusulkan target bahwa energi terbarukan akan mencapai lebih dari 30 persen dari total konsumsi energi primer dan lebih dari 60 persen konsumsi energi primer kapasitas baru di negara percontohan pada tahun 2025.

Skema tersebut juga meminta otoritas lokal untuk "menderegulasi" dan meningkatkan administrasi industri energi terbarukan mereka.

Pengumuman tersebut muncul di tengah dorongan ambisius untuk meningkatkan kapasitas energi terbarukan negara. China memasang 152 gigawatt (GW) kapasitas energi terbarukan tahun lalu, mewakili 76,2 persen dari seluruh kapasitas energi baru.

Presiden Xi Jinping Tiba di Rusia untuk Bertemu Vladimir Putin

China telah mengatakan pihaknya bertujuan agar energi terbarukan mencapai lebih dari 50 persen dari kapasitas pembangkit listriknya pada tahun 2025, dengan sebagian besar dipasang di daerah berpenduduk jarang, sebagian besar pedesaan seperti Mongolia Dalam dan provinsi Gansu.

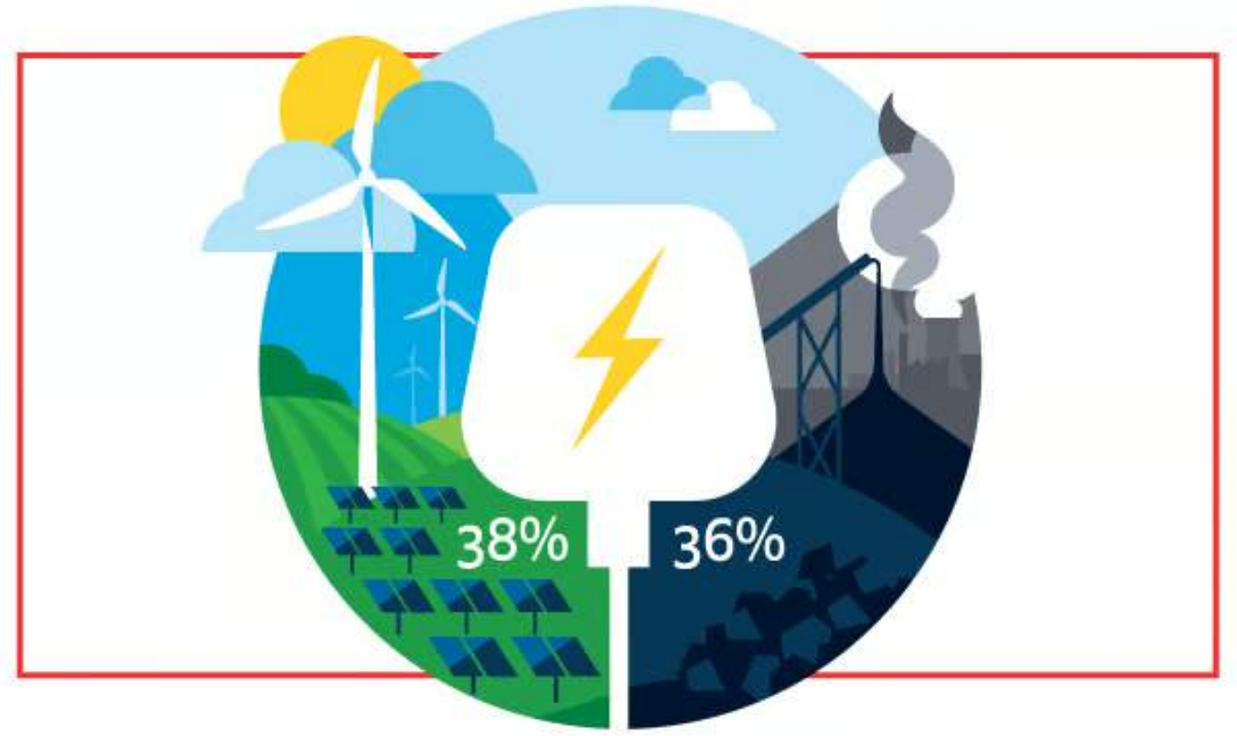
Data point: renewable energy use is on the rise

PUBLISHED 12 MAY, 2022 • 2 MIN READ

As the world recovers from a pandemic and economies begin to rebound, there has never been a greater demand for electricity.



Throughout 2021 clean energy sources generated 38% of the world's electricity. Combined, all clean energy sources generated more of the world's electricity than coal, which contributed 36%.

Wind and solar power growth on track to meet targets

Now, for the first time, clean energy is overtaking coal, and the use of renewables continues to rise. In 2021, wind turbines and solar panels generated more than a tenth (10.3%) of global electricity, up from 9.3% in the previous year, according to analysis from climate and energy think-tank Ember.

Throughout 2021 clean energy sources generated 38% of the world's electricity, suggesting that global wind and solar growth is on track to meet climate targets. Ember's study found that solar generation rose by 23% globally, and wind by 14%. If the ten-year average compound growth rate of 20% can be maintained to 2030, solar and wind power could grow enough to limit global heating to 1.5°C, according to the analysis.

This shows that the green energy transition is well on its way. However, green shifts in global electricity still need to sustain very high growth rates to replace coal and reduce emissions.

Fossil fuels still feeding energy needs

Indeed, the rising demand for electricity has pushed a surge in fossil fuel use. While clean sources have grown, coal-fired electricity generation increased by 9% in 2021, the fastest rate since 1985. Countries across Asia saw the steepest rise in coal use in order to meet the booming demand for electricity in the region—China saw a 9% rise, India 11%, and Mongolia 13%.

Fossil fuel companies have reaped the rewards of higher demand. As many regions of the world fell into an energy crisis post-pandemic—a crisis which has only been exacerbated by Russia's invasion of Ukraine and uncertainty over energy supply—oil giants Shell and BP reported record-breaking profits in the first quarter of 2022.

Keeping up with clean energy growth

Combined, all clean energy sources generated more of the world's electricity than coal, which contributed 36% in 2021.

The Ember analysis found that the Netherlands, Australia and Vietnam had the fastest growth rates for renewable sources, as they shifted over 8% of their total electricity demand to wind and solar in just the last two years. As many as 50 countries have now switched at least 10% of their electricity generation from fossil fuels to cleaner sources.

With this milestone in wind and solar, and major economies like the UK, the US, Canada and Germany planning to shift their grids to 100% green electricity within the next 15 years, the Ember study claims that it is now "eminently possible" to keep the rld's rise in temperature under 1.5°C.

DEN sebut Papua memiliki potensi besar pengembangan energi terbarukan

Ardiles Leloltery

Salah satu wilayah di Papua yang memiliki potensi tenaga air ialah Mamberamo.

Jayapura (ANTARA) - Dewan Energi Nasional (DEN) menyebutkan bahwa Papua memiliki potensi besar dalam pengembangan energi terbarukan terutama hydropower (tenaga air) untuk aliran listrik.

Anggota pemangku kepentingan Dewan Energi Nasional Musri Mawaleda dalam siaran pers yang diterima di Jayapura, Sabtu, mengatakan salah satu wilayah di Papua yang memiliki potensi tenaga air ialah Mamberamo.

"Di wilayah Mamberamo itu berdasarkan hasil studi awal diketahui mempunyai potensi kelistrikan sekitar 23 ribu megawatt, sehingga bisa memasok separuh dari keseluruhan Papua termasuk Papua Nugini jika itu dikembangkan," katanya lagi.

Menurut Musri, ke depan jika potensi tersebut dapat berjalan baik, maka wilayah Mamberamo akan berkembang tidak hanya untuk industri energi saja tetapi juga terkait dengan pertanian, gas, dan sebagainya.

Pihaknya telah melakukan pertemuan dengan DPR Papua untuk mendorong percepatan penyelesaian Peraturan Daerah (Perda) tentang Rencana Umum Energi Daerah (RUED) Provinsi Papua pada Kamis (9/2).

Hal tersebut, kata dia pula, sebagaimana diamanatkan oleh peraturan perundang-undangan bahwa RUED Provinsi Papua harus mengacu pada Rencana Umum Energi Nasional (RUEN), sehingga pembangunan pengelola energi beserta infrastruktur pendukung di Papua bisa terintegrasi secara nasional.

Dia menjelaskan penyusunan naskah akademik beserta draf RUED telah diselesaikan oleh pihak eksekutif dibantu akademisi dari Universitas Cenderawasih, Jayapura.

"Kami mendorong agar DPRP segera melakukan pembahasan dan penetapan Raperda RUED, mengingat saat ini 34 provinsi di Indonesia, 28 di antaranya telah selesai dan tinggal empat provinsi yang belum termasuk Papua, sehingga kami minta dapat diselesaikan secepatnya," ujarnya lagi.

Dia menambahkan materi muatan tentang RUED mengatur penawaran (supply) dan permintaan (demand) energi, sehingga dengan adanya Perda RUED tentu antara supply dan demand mulai dari energi listrik hingga energi primer bisa diatur dan dikendalikan.

Ia mengatakan misalnya energi listrik seperti bahan bakar minyak (BBM) dan gas dari sejumlah kasus yang terjadi di daerah termasuk di Papua adanya kelangkaan BBM dan gas yang akhirnya menimbulkan antrean di SPBU maupun depot yang akar persoalannya akibat tidak ada perencanaan yang baik antara supply dan demand.

"Padahal jika ada perencanaan yang baik tentu akan menjawab kebutuhan energi di daerah, mengingat selama ini permintaan energi kepada perusahaan mandatory hanya berdasarkan asumsi atau perkiraan dari perusahaan mandatory yang datang di daerah," katanya pula.

Ketua DPR Papua Jhony Banua Rouw mengatakan pada prinsipnya pihaknya siap menyelesaikan rancangan Perda tentang REUD sebagaimana diamanatkan dalam UU Nomor 30 Tahun 2017 tentang Energi.

"Namun kami juga ingin mengetahui tujuan dan urgensi serta manfaat RUED yang berdampak langsung kepada Orang Asli Papua (OAP) maupun masyarakat Papua pada umumnya," katanya pula.

Ini Cara Dorong Bauran Energi Nasional Lewat Pembangunan PLT - Medcom.id

Arif Wicaksono

Jakarta: Akselerasi bauran energi di Indonesia memerlukan kolaborasi antar pihak guna mewujudkan pemanfaatan energi baru terbarukan yang agresif. Dilansir dari Kementerian Energi dan Sumber Daya Mineral (KESDM), hingga saat ini bauran energi nasional tercatat di angka 14,11 persen.

Angka tersebut menuntut berbagai pihak untuk melakukan upaya out of the box guna mengakselerasi pemenuhan target bauran energi tersebut. Cara untuk mencapainya salah satunya dengan menggaet pihak swasta dalam mendukung perkembangan industri Pembangkit Listrik Tenaga Surya (PLTS).

Koordinator Pelayanan dan Pengawasan Usaha Aneka EBT Kementerian ESDM Mustaba Ari menuturkan apresiasinya terhadap perusahaan pengembang energi surya yang telah menyediakan wadah bagi para mitra bisnis dan organisasi untuk saling belajar, sekaligus memberikan dampak terhadap kemajuan energi baru terbarukan di Indonesia.

"Kami saat ini terus memonitor perkembangan industri PLTS, dan turut menyampaikan kehadiran regulasi mengenai PLTS Atap diharapkan mampu dilihat menjadi peluang bagi pelaku industri PLTS Atap," jelas dia, dikutip dari *Antara*, Kamis, 23 Maret 2023.

Bagaimana tanggapan anda mengenai artikel ini?

Representatif PLN Icon Plus Anne Aprina Priskila mengatakan saat ini PLN Icon Plus selaku bagian dari Grup PLN terus mengkoordinasikan beragam upaya bagi industri PLTS Atap terutama dalam hal perizinan.

"Selain itu kami juga sedang mengembangkan sebuah sistem yang mampu memonitor penggunaan listrik yang tersambung dalam jaringan. Kami berharap melalui upaya yang kami lakukan dapat turut serta mendukung misi peningkatan akses energi terbarukan di Indonesia," ujar Anne.

PLTS di daerah tertinggal

Sebagai salah satu perusahaan pengembang proyek energi surya di Indonesia, SUN Energy kembali berkolaborasi bersama pemerintah, mitra bisnis, dan organisasi generasi muda. SUN Energy berkolaborasi bersama Society of Renewable Energy (SRE Indonesia) menjalankan program elektrifikasi sistem PLTS di tiga desa terpencil dan tertinggal selama 2022.

Direktur Utama PT Surya Utama Nuansa (SUN Energy) Roy Wijaya mengungkapkan SUN Energy turut memberikan dampak terhadap masyarakat dan lingkungan melalui program elektrifikasi wilayah yang belum mendapatkan aliran listrik secara optimal.

"Sebelumnya kami telah mengaliri 19 desa di Indonesia, dan pada hari ini, kami kembali memulai inisiatif kami untuk mengalirkan listrik desa-desa melalui pemanfaatan energi bersih, salah satunya di Desa Paya Cut, Kabupaten Bireun, D.I Aceh," ungkap Roy Wijaya.

Jenis-Jenis Sumber Energi di Bumi, Terbarukan dan Tak Terbarukan

Rheza Aditya Gradianto

Bola.com, Jakarta - Jenis-jenis sumber **energi** digunakan untuk menghasilkan listrik, membuat sesuatu bergerak, dan mempermudah pekerjaan yang dilakukan oleh manusia dalam kehidupan sehari-hari.

Ketika populasi dunia meningkat, permintaan energi untuk memberi daya pada rumah, bisnis, dan komunitas kita pasti juga turut meningkat.

Secara umum, sumber energi terdiri dari **energi** terbarukan dan tak terbarukan. Energi terbarukan adalah sumber daya alam yang tersedia berlimpah di alam dan berkelanjutan. Energi tak terbarukan merupakan energi yang bisa habis seiring berjalannya waktu.

Energi memliki beberapa macam bentuk, setiap bentuknya memiliki manfaat sesuai kegunaannya masing-masing.

Untuk mempelajarinya lebih lanjut, kamu bisa membaca artikel mengenai berbagai jenis energi di bawah ini.

Berikut jenis-jenis sumber energi yang ada di bumi, terbarukan dan tak terbarukan, disadur dari *Liputan6*, Kamis (16/2/2023).

Berita Video, McLaren Rilis Mobil Baru untuk Formula 1 Musim Depan pada Senin (13/2/2023)

Ilustrasi sungai. Credit: pexels.com/Jon

1. Energi air

Sumber energi air atau tenaga air adalah satu di antara sumber energi terbarukan tertua dan terbesar. Jenis pembangkit listrik tenaga air yang paling umum menggunakan bendungan di sungai untuk menyimpan air di reservoir.

Air yang dilepaskan dari reservoir mengalir melalui turbin, memutarnya, yang pada gilirannya mengaktifkan generator untuk menghasilkan listrik.

Energi Biomassa

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

ergi biomassa adalah jenis-jenis sumber energi yang dihasilkan dari bahan organik. Energi biomassa terbuat dari bahan yang berasal dari organisme hidup, seperti tumbuhan dan hewan.

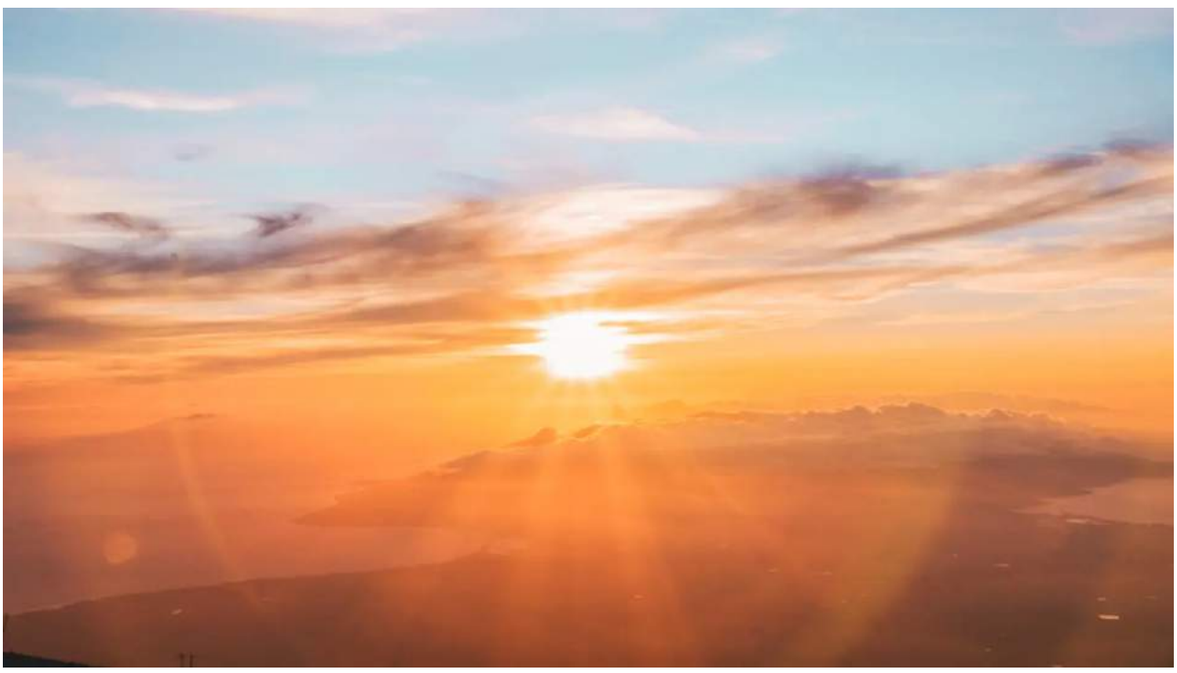
Bahan biomassa yang paling umum digunakan untuk energi adalah tanaman, kayu, dan limbah.

3. Energi pasang surut

Energi pasang surut menggunakan naik turunnya pasang surut air laut untuk mengubah energi kinetik pasang surut yang masuk dan keluar menjadi energi listrik. Pembangkitan energi melalui tenaga pasang surut paling umum di daerah pesisir.

Energi pasang surut merupakan satu di antara sumber energi terbarukan dan menghasilkan energi yang besar bahkan pada saat pasang surut dengan kecepatan rendah.

Jenis-Jenis Sumber Energi di Bumi yang Terbarukan



Ilustrasi matahari. Credit: unsplash.com/Andrea

4. Energi matahari

Matahari adalah sumber energi utama di bumi. Sumber energi dari matahari disebut tenaga surya. Tenaga surya adalah energi dari matahari yang diubah menjadi energi panas atau listrik.

Energi ini bisa bermanfaat untuk menghasilkan listrik, menyediakan cahaya atau lingkungan interior yang nyaman, atau keperluan komersial dan industri.

5. Energi angin

Tenaga angin atau energi angin menggambarkan proses di mana angin digunakan untuk menghasilkan tenaga mekanik atau listrik. Sumber energi ini biasanya didapat dari turbin angin yang mengubah energi kinetik angin menjadi tenaga mekanik.

Tenaga mekanik dapat digunakan untuk tugas-tugas tertentu seperti memompa air.

6. Energi panas bumi

Energi panas bumi adalah panas di dalam bumi. Energi panas bumi merupakan sumber energi terbarukan karena panas terus-menerus diproduksi di dalam bumi. Energi panas ini disimpan dalam batuan dan cairan di pusat bumi.

7. Energi nuklir

ergi nuklir adalah energi dalam nukleus (inti) suatu atom. Atom adalah partikel kecil yang

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

nyusun setiap objek di alam semesta. Sumber energi ini dapat dihasilkan dengan dua cara: fisi ketika inti atom terpecah menjadi beberapa bagian – atau fusi – ketika inti bergabung bersama.

Sumber energi nuklir yang dimanfaatkan di seluruh dunia saat ini untuk menghasilkan listrik adalah melalui fisi nuklir, sedangkan teknologi untuk menghasilkan listrik dari fusi berada pada fase R&D.

Jenis-Jenis Sumber Energi di Bumi yang Tak Terbarukan

Ilustrasi gas. (dok. Pixabay.com/PublicDomainPictures/Putu Elmira)

1. Gas alam

Gas alam adalah hidrokarbon tak terbarukan yang digunakan sebagai sumber energi untuk pemanasan, memasak, dan pembangkit listrik.

Sumber energi ini juga digunakan sebagai bahan bakar untuk kendaraan dan sebagai bahan baku kimia dalam pembuatan plastik dan bahan kimia organik penting lainnya secara komersial.

2. Mineral bumi

Mineral bumi dan bijih logam adalah contoh macam-macam sumber energi yang tidak dapat diperbarui. Jenis sumber daya mineral yang digunakan bervariasi menurut teknologi.

Dalam geologi dan mineralogi, mineral adalah senyawa kimia padat dengan komposisi kimia yang cukup jelas dan struktur kristal spesifik yang terjadi secara alami dalam bentuk murni.

3. Bijih logam

Logam hadir dalam jumlah besar di kerak bumi, dan ekstraksinya oleh manusia hanya terjadi di mana mereka terkonsentrasi oleh proses geologis alami.

Deposit bijih logam yang terlokalisasi di dekat permukaan yang dapat diekstraksi secara ekonomis oleh manusia tidak dapat diperbarui dalam kerangka waktu manusia.

Jenis-Jenis Sumber Energi di Bumi yang Tak Terbarukan

Ilustrasi bensin. | Pexels.com

4. Minyak bumi

Minyak bumi adalah bahan bakar fosil. Ini terbentuk ketika panas dan tekanan menekan sisa-sisa tanaman prasejarah, hewan, dan kehidupan air di bawah dasar laut atau danau selama jutaan tahun sehingga menjadi bahan bakar fosil.

Minyak mentah adalah sumber daya tak terbarukan yang menumpuk dalam bentuk cair di antara lapisan kerak bumi. Ini diambil dengan mengebor ke dalam tanah dan dasar laut dan memompa cairan keluar. Cairan tersebut kemudian dimurnikan dan digunakan untuk membuat banyak produk berbeda.

5. Batu bara

Batu bara terutama digunakan sebagai bahan bakar untuk menghasilkan tenaga listrik. Panas yang dihasilkan oleh pembakaran batu bara digunakan untuk mengubah air menjadi uap bertekanan tinggi yang menggerakkan turbin, yang menghasilkan listrik.

Kapasitas Produksi Energi pada Beberapa Pembangkit Listrik Tenaga Panas Bumi di Indonesia - GoodStats Data

GoodStats Data

Penerapan energi terbarukan saat ini masih di bawah target. Indonesia masih tertinggal dalam pengembangan energi terbarukan dibandingkan dengan rencana pengembangan energi dan kapasitas yang berbeda. Meskipun ada beragam opsi peraturan dan mekanisme dukungan, kurangnya kebijakan yang konsisten dan mendukung untuk mengembangkan pembangkit listrik tenaga surya telah menjadi salah satu hambatan terbesar dalam penerapan energi surya.

Saat ini, hanya sebagian kecil listrik di Indonesia yang berasal dari energi terbarukan, yaitu hanya 2% dari total potensi energi terbarukan yang tersedia di Indonesia. Pembangkit listrik tenaga fosil diperkirakan akan terus mendominasi sistem listrik di Jawa-Bali, namun RUPTL 2021-2030 dan strategi untuk beralih dari batu bara dalam jangka panjang dapat membalikkan tren ini untuk mendukung penggunaan energi terbarukan.

Meskipun tantangan dalam pengembangan energi terbarukan, PLN telah mencapai beberapa kemajuan dalam mencapai target campuran energi terbarukan yang diumumkan dalam RUPTL 2021-2030. Bagian energi terbarukan di Indonesia pada tahun 2021 tercatat sebesar 11,5%. Komitmen PLN untuk mencapai campuran energi terbarukan 23% pada tahun 2025 termaktub dalam RUPTL 2021-2030. Baru-baru ini, PLN menandatangani perjanjian pembelian tenaga listrik pada aset geothermal terkonsolidasi yang dimiliki oleh PLN, PT Indonesia Power, dan PT Pertamina Geothermal Energy.

Meskipun demikian, masih dibutuhkan kebijakan konsisten dan mendukung untuk mendukung pengembangan energi terbarukan di Indonesia. Seiring dengan rencana untuk beralih dari batu bara dalam jangka panjang, pengembangan energi terbarukan harus terus didorong dan didukung untuk mencapai target penggunaan energi terbarukan yang lebih besar di masa depan.

Rencana Pengembangan Pembangkit Nasional Beri Porsi EBT Lebih Besar

Rencana Pengembangan Pembangkit Nasional Beri Porsi EBT Lebih Besar

Rabu, 1 Februari 2023 - Dibaca 563 kali

KEMENTERIAN ENERGI DAN SUMBER DAYA MINERAL

REPUBLIK INDONESIA

SIARAN PERS

NOMOR: 041.Pers/04/SJI/2023

Tanggal: 1 Februari 2023

Rencana Pengembangan Pembangkit Nasional Beri Porsi EBT Lebih Besar

Pemerintah terus berkomitmen untuk mempercepat pencapaian Net Zero Emission (NZE) di tahun 2060 atau lebih cepat. Di sektor energi, salah satu upayanya mendorong porsi kapasitas pembangkit energi baru dan terbarukan (EBT) menjadi lebih besar daripada porsi pembangkit dari energi fosil.

Rencana Umum Penyediaan Tenaga Listrik (RUPTL) PLN teranyar tahun 2021-2030, memberikan porsi lebih besar bagi pembangkit EBT, yakni 52 persen, dibandingkan pembangkit energi fosil yang hanya 48%. Sehingga, RUPTL ini disebut "RUPTL Hijau".

"Dalam RUPTL kita sama-sama paham kalau 52% dari pembangkit kita itu basisnya adalah EBT," ujar Plt. Direktur Jenderal Ketenagalistrikan Dadan Kusdiana, dalam Konferensi Pers Capaian Kinerja Sektor Ketenagalistrikan Tahun 2022 dan Capaian Tahun 2023, Selasa (31/1).

Maka dari itu, pada rencana pengembangan pembangkit nasional ke depan, tegas Dadan, Pembangkit trik Tenaga Uap (PLTU) yang dibangun hanyalah PLTU yang sudah ditetapkan dalam RUPTL

belum berlakunya Peraturan Presiden Nomor 112 Tahun 2022 tentang Percepatan Pengembang Energi Terbarukan Untuk Penyediaan Tenaga Listrik.

"Kita sudah memastikan bahwa tidak ada lagi PLTU baru, kecuali yang sudah ditetapkan dalam RUPTL sebelum berlakunya Perpres 112 Tahun 2022," ujar Dadan.

Selanjutnya, Dadan menjelaskan, pengembangan PLTU baru diperbolehkan apabila terintegrasi dengan industri yang dibangun berorientasi untuk peningkatan nilai tambah sumber daya alam, seperti smelter, atau PLTU yang termasuk dalam Proyek Strategis Nasional (PSN) yang berkontribusi besar terhadap penciptaan lapangan kerja dan/atau pertumbuhan ekonomi nasional.

"Syarat yang kedua adalah dalam 10 tahun, harus menurunkan emisi Gas Rumah Kaca (GRK), kan kalau PLTU dari batubara, harus menurukan emisi sebesar minimal 35% dan 35% ini cukup berat, ini adalah angka di mana Pemerintah dan seluruh stakeholder berkomitmen untuk terus melakukan upaya penurunan emisi GRK, ini pun menjadi syarat utama untuk mendapatkan pengecualian pembangunan PLTU," terang Dadan.

Adapun syarat yang ketiga, lanjut Dadan, adalah beroperasi paling lama sampai tahun 2050. "Jadi kalau tahun 2030, ya 20 tahun kemudian harus istirahat atau pensiun," imbuhnya.

Berdasarkan RUPTL 2021-2030, diproyeksikan total tambahan kapasitas pembangkit adalah 40,575 Gigawatt (GW), dengan porsi pembangkit EBT sebesar 20,923 GW atau 51,6% dan porsi pembangkit fosil sebesar 19,562 GW atau 48,4%.

Berdasarkan jenis pembangkitnya, pembangkit dengan sumber EBT terbesar adalah Pembangkit Listrik Tenaga Air/Mikro/Mikrohidro (10,391 GW), kemudian Pembangkit Listrik Tenaga Surya (4,68 GW), Pembangkit Listrik Tenaga Panas Bumi (3,355 GW), PLT EBT Base (1,01 GW), lalu Pembangkit Listrik Tenaga Bayu (0,597 GW), PLT Bio (0,590 GW), dan BESS (0,3 GW).

Sementara untuk pembangkit dengan sumber energi fosil, PLTU menempati porsi terbesar dengan 13,819 GW, kemudian Pembangkit Listrik Tenaga Uap/Gas Uap/Mesin Gas dengan 5,828 GW, dan Pembangkit Listrik Tenaga Diesel dengan 5 Megawatt (MW).

Berdasarkan jenis pengembang, Independent Power Producer (IPP) mengambil porsi terbesar untuk pengembangan pembangkit hingga tahun 2030, yakni 26,006 GW atau 64%, kemudian PLN sebanyak 14,269 GW atau 35%, dan kerja sama antar wilayah usaha sebesar 300 MW atau 1% saja.

Dadan juga mengungkapkan bahwa saat ini pembahasan teknis untuk meninjau kembali RUPTL 2021-2030 sudah dimulai. Menurutnya, jika memang dipandang perlu adanya perubahan RUPTL, maka akan dilakukan revisi, dengan tidak menurunkan target pembangunan pembangkit.

"Sekarang sudah mulai pembahasan teknis untuk mereview RUPTL yang sedang berjalan ini, kalau dipandang perlu nanti akan dilakukan revisi. Tetapi saya sudah sampaikan bahwa dengan review ini, jika ada revisi tidak menurunkan target (pengembangan EBT)," tegasnya. (DKD)

Komitmen Hijau, Entitas TBS Utama (TOBA) Teken Pengembangan Energi Terbarukan

EmitenNews.com - Energi Baru TBS (EBT), anak usaha TBS Energi Utama (TOBA) bersama PT Adaro Clean Energy Indonesia, dan PT Medco Power Indonesia meneken Memorandum of Understanding (MoU) pengembangan energi terbarukan. Selain itu, teken nota kesepahaman tersebut juga untuk peluang industrialisasi rantai pasok solar PV/BESS di Indonesia.

Sebelumnya, Pemerintah Indonesia dan Singapura telah meneken nota kesepahaman mengenai kerja sama investasi pengembangan industri dan kapabilitas manufaktur energi terbarukan hulu dan hilir di Indonesia dalam Pertemuan Pemimpin Singapura-Indonesia di Singapura pada Kamis, (16/3).

Teken nota kesepahaman itu, dilakukan Direktur Utama Energi Baru TBS (EBT) Dimas Adi Wibowo, Presiden Direktur Adaro Clean Energy Indonesia (Adaro) Dharma Hutama Djojonegoro, dan Presiden Direktur Medco Power Indonesia (Medco Power) Eka Satria.

Penandatanganan nota kesepahaman menjadi wujud keseriusan EBT, dan perusahaan lain dalam membangun iklim rantai pasok solar PV, dan sistem penyimpanan energi baterai (SPEB) di Indonesia. EBT berkomitmen mendukung program pemerintah Indonesia dalam mewujudkan cita-cita meningkatkan produksi dalam negeri, terutama industri rantai pasok solar PV/SPEB di Indonesia.

Dalam kerja sama itu, EBT akan memanfaatkan MoU kerja sama energi terbarukan antara Indonesia dan Singapura untuk memfasilitasi investasi dalam pengembangan industri manufaktur energi terbarukan Indonesia, termasuk fotovoltaik surya (PV), dan Sistem Penyimpanan Energi Baterai (BESS), memanfaatkan investasi proyek ekspor listrik ke Singapura sebagai permulaan, dan secara strategis untuk pengembangan kelistrikan nasional lebih terintegrasi.

“Kami menyambut baik, dan mendukung upaya pemerintah mempercepat pengembangan industri energi terbarukan Indonesia. Kerja sama ini akan memperkuat kontribusi kami dalam pengembangan proyek-proyek energi terbarukan yang eksisting, dan baru untuk masa depan Indonesia lebih hijau,” tutur Dimas Adi Wibowo, Direktur Utama EBT.

Penandatanganan nota kesepahaman itu, merupakan komitmen perusahaan-perusahaan pembangkit listrik Indonesia untuk mempromosikan pengembangan infrastruktur, dan industri energi terbarukan, terutama energi surya, sebagai sumber energi terbarukan terbesar akan berkontribusi lebih dari 50 persen dari pembangkitan listrik domestik pada 2060.

Langkah tersebut sejalan komitmen Towards a Better Society 2030 (TBS 2030). Di mana, TBS telah menetapkan inisiatif untuk memangkas emisi karbon, meningkatkan kualitas lingkungan, meningkatkan kesejahteraan sosial, dan meningkatkan tata kelola perusahaan.

Langkah TBS melalui EBT tersebut juga akan mencakup proyek-proyek pembangkit listrik tenaga surya, fasilitas manufaktur dari rantai pasok panel surya, dan BESS. Dengan demikian, EBT dan mitra-mitra bisnis berharap dapat memberikan dampak positif bagi lingkungan, masyarakat, dan ekonomi Indonesia. (*)

Mau Transisi Energi Jangan Sendirian! - Medcom.id

Ade Hapsari Lestarini

Jakarta: Transisi energi menjadi salah satu upaya menjaga ketahanan energi dan mewujudkan ekonomi hijau di Indonesia. Hal ini guna mencapai target *Net Zero Emission* (NZE) pada 2060 dan pengurangan 32 persen emisi pada 2030.

Dalam mendukung percepatan transisi energi di dalam negeri, Pemerintah juga telah menerbitkan Peraturan Presiden Nomor 112 Tahun 2022 tentang Percepatan Pengembangan Energi Terbarukan untuk Pengembangan proyek EBT guna mendorong target jangka menengah untuk penurunan emisi Indonesia 2030.

Transisi energi juga menunjukkan komitmen Indonesia untuk memperluas akses terhadap teknologi yang terjangkau dan bersih guna mendorong pemulihan ekonomi yang berkelanjutan dan lebih hijau. Pemerintah telah meningkatkan target komposisi Energi Baru dan Terbarukan (EBT) dalam bauran energi menjadi sebesar 23 persen pada 2025 dan 31 persen pada 2050.

Bagaimana tanggapan anda mengenai artikel ini?

Terlebih lagi potensi EBT Nasional tercatat sebesar 3.689 gigawatt (GW), yang terdiri atas surya, hidro, bioenergi, angin, panas bumi, dan laut yang tersebar di berbagai wilayah Indonesia. Total pemanfaatan yang telah dilakukan sebesar 12.557 MW atau 0,3 persen dari total potensi.

Pemerintah pun terus melakukan percepatan transisi energi dan hilirisasi mineral nasional. Salah satu upaya untuk mendukung hal tersebut adalah berkolaborasi dengan Kementerian Energi dan Sumber Daya Mineral (ESDM) dan Kementerian Perindustrian (Kemenperin) dalam Tripatra Energy Talk bertajuk "Kolaborasi Nasional untuk Percepatan Transisi Energi dan Hilirisasi Mineral".

Kegiatan ini bertujuan untuk mendorong diskusi tentang kolaborasi dan pembangunan kapabilitas nasional untuk mendukung program transisi energi dan hilirisasi mineral nasional sekaligus menjadi wadah untuk mengumpulkan wawasan tentang masa depan energi dan mineral dari para pakar dan praktisi.

President Director & CEO PT Tripatra Engineers and Constructors (Tripatra) Raymond Naldi Rasfuldi, mengatakan, perseroan terus mendorong perubahan transformasional dan berkelanjutan dengan visi "Membangun Solusi Berkelanjutan untuk Transformasi Energi dan Percepatan Hilirisasi". Kolaborasi ini untuk mengimplementasikan visi tersebut serta ikut berkontribusi dalam memajukan sektor energi dan mineral nasional.

"Kami sangat bangga dapat berkolaborasi dengan pemerintah dalam mendukung upaya percepatan transisi energi dan hilirisasi mineral nasional. Kami siap untuk terus ikut berkontribusi dalam membangun kapabilitas nasional dan memajukan sektor ini bersama-sama dengan pemerintah dan pelaku industri lainnya," jelas Raymond Naldi Rasfuldi, dalam keterangan tertulisnya, Kamis, 23 Maret 2023.

Transisi energi bentuk ekosistem terintegrasi

Direktur Perencanaan dan Pembangunan Infrastruktur, Energi Baru, Terbarukan dan Konservasi Energi (EBTKE) Kementerian ESDM Hendra Iswahyudi menyatakan, Kementerian ESDM berkomitmen untuk mempercepat transisi energi dengan membentuk ekosistem yang sinergis dan terintegrasi antara pemerintah, media, akademik, industri (BUMN dan Swasta), dan masyarakat.

"Kami percaya dengan membentuk ekosistem yang sinergitas melalui konsep pentahelix antarpemangku kepentingan, kita dapat mempercepat pengembangan EBTKE dalam transisi energi di Indonesia sehingga memberikan manfaat jangka panjang bagi masyarakat dan lingkungan. Kementerian ESDM juga sangat menyambut baik kolaborasi dengan berbagai pihak, salah satunya seperti yang dilakukan bersama Tripatra untuk semakin memperkaya pengetahuan serta menguatkan sinergi dan kolaborasi nasional seluruh pemangku kepentingan," jelas Hendra.

Selain transisi energi, hilirisasi mineral juga tidak kalah penting untuk terus didorong. Sebab, hilirisasi merupakan strategi untuk meningkatkan nilai tambah komoditas yang dimiliki oleh suatu negara. Dengan hilirisasi, komoditas yang diekspor tidak lagi berwujud bahan baku mentah tetapi sudah menjadi barang setengah jadi.

Salah satunya seperti kebijakan hilirisasi dan pelarangan ekspor nikel mentah (bijih nikel) yang telah berhasil mendongkrak tambah ekspor produk nikel Indonesia. Dimana harga nikel yang telah diolah di smelter dapat memiliki nilai tambah lebih 300 kali dibandingkan bijih nikel. Data Badan Pusat Statistik (BPS) menunjukkan total nilai ekspor mencapai

PERPUSTAKAAN NASIONAL

95,98 miliar pada 2022, naik 365,4 persen dibandingkan 2021 yang mencapai USD1,28 miliar.

Selain meningkatkan nilai tambah komoditas, adanya hilirisasi diharapkan dapat memperkuat struktur industri, serta meningkatkan peluang usaha dalam negeri dengan tersedianya lapangan pekerjaan baru. Sehingga dapat menunjang pembangunan nasional yang berkelanjutan guna mewujudkan kesejahteraan dan kemakmuran rakyat secara berkeadilan.

Hilirisasi strategi majukan industri nasional

Menurut Direktur Industri Logam Kementerian Perindustrian (Kemenperin) Liliek Widodo, hilirisasi mineral merupakan strategi penting untuk memajukan industri nasional dan meningkatkan nilai tambah produk sumber daya mineral dalam negeri.

Percepatan hilirisasi mineral akan membawa dampak positif bagi industri nasional, seperti peningkatan inovasi teknologi, peningkatan nilai tambah produk, dan penciptaan lapangan kerja baru. Dengan terciptanya kemampuan nasional dalam mengolah mineral, Indonesia akan dapat memanfaatkan potensi sumber daya mineral yang dimiliki secara optimal.

"Hal ini juga sejalan dengan visi pemerintah dalam menciptakan industri yang lebih maju dan berdaya saing bahkan bukan tidak mungkin dapat menjadi produsen mineral yang berkontribusi besar dalam perekonomian global. Namun, untuk mencapainya, perlu ada kolaborasi yang baik antara pemerintah dan sektor swasta untuk terus menciptakan kemampuan nasional yang kuat dalam hal teknologi, sumber daya manusia, dan infrastruktur untuk dapat melaksanakan hilirisasi mineral dengan efektif dan efisien," tutur Liliek.

Di sisi lain, Tripatra juga mengumumkan kerja sama yang sudah dilakukan dalam bidang transisi energi dan hilirisasi mineral antara lain kerja sama antara PT Kaltim Parna Industri, Tripatra, dan Nextchem untuk studi kelayakan 300 tpd *green ammonia production plant*, Tripatra dan HDF Energy untuk pengembangan Hydrogen to Power (HyPower) project, Tripatra dan METDevelopment untuk pengembangan *biofuels* generasi kedua di Indonesia.

Kemudian kerja sama antara Indika Energy, Altilium, Terra Altilium Berdaya, Geofix, dan Tripatra untuk studi kelayakan DNi Technology untuk pengolahan bauksit, serta kerja sama Tripatra dan Emirates Global Aluminum (EGA) untuk pengembangan smelter aluminium di Indonesia.

"Komitmen Tripatra dalam percepatan transisi energi dan hilirisasi mineral telah kami wujudkan dalam berbagai bentuk kerja sama. Mulai dari sektor panas bumi (geotermal), studi *green* amonia, pengembangan 2nd *generation biofuel*, sampai pengembangan di sektor aluminium dan nikel. Kolaborasi ini merupakan inisiatif yang penting untuk membangun kapabilitas nasional mendukung Indonesia mencapai tujuan berkelanjutan dan meningkatkan nilai tambah dari sumber daya alam Indonesia," tutup Raymond Naldi Rasfuldi.

Miris! Punya Harta Karun Ini, Tapi RI Gak Punya Pabriknya

Firda Dwi Muliawati

Foto: Cantiknya Pulau Messah, Pulau Berselimut Panel Surya di Timur RI. CNBC Indonesia/Gustidha Budiartie

Jakarta, CNBC Indonesia - Indonesia memiliki sumber "harta karun" energi yang melimpah. Tak hanya batu bara atau pun gas bumi, Indonesia ternyata memiliki "harta karun" energi baru terbarukan (EBT) yang besar.

Adapun salah satu "harta karun" energi baru terbarukan RI yang besar yakni energi matahari atau surya.

Berdasarkan data Kementerian Energi dan Sumber Daya Mineral (ESDM) pada tahun 2021, potensi energi surya di Indonesia tak main-main jumlahnya yakni mencapai 207,8 Giga Watt (GW). Maka, tak salah bila energi surya ini disebut sebagai salah satu 'harta karun' energi RI.

Namun sayangnya, besarnya potensi energi surya di Indonesia belum dimanfaatkan secara optimal untuk sumber energi di Tanah Air. Bahkan, pabrik pembuatan panel surya pun belum ada di negeri ini.

Direktur Jenderal Energi Baru Terbarukan dan Konservasi Energi (EBTKE) Kementerian ESDM, Dadan Kusdiana mengungkapkan bahwa Indonesia memiliki potensi besar dalam pengembangan energi baru terbarukan dari surya. Namun sayangnya, dia mengakui bahwa RI belum memiliki pabrik untuk membuat panel surya yang nantinya bisa menghasilkan listrik.

"Kita punya energi terbarukan (energi surya) tapi kita tidak punya pabriknya untuk mengolah. Jadi nanti kita dorong pabriknya (di Indonesia)," ungkap Dadan saat ditemui di Kantor Kementerian ESDM, Kamis (16/3/2023).

Perlu diketahui, sepanjang 2022 lalu, kapasitas pembangkit EBT bertambah sebesar 1.004 MW. Dengan demikian, kapasitas terpasang pembangkit EBT secara nasional secara total telah mencapai 35 MW hingga 2022.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

n, dari 12.535 MW pembangkit energi baru terbarukan tersebut, kapasitas terpasang Pembang Listrik Tenaga Surya (PLTS) "hanya" sebesar 250 Mega Watt peak (MWp). Artinya, kapasitas PLTS baru 2% dari total kapasitas pembangkit berbasis energi baru terbarukan.

Bila dibandingkan dengan potensinya yang mencapai 207,8 GW, artinya pemanfaatan energi surya untuk menjadi sumber energi listrik masih di bawah 1%, tepatnya 0,12%.

Meski demikian, pemerintah meyakini pemanfaatan PLTS ini ke depannya akan semakin berkembang.

Dadan melanjutkan, selama ini Indonesia hanya mengimpor panel surya. Dengan begitu, dia mengatakan dalam jangka panjang, Indonesia akan bangun industri PLTS mulai dari hulu hingga hilirnya. Dengan demikian, Indonesia bisa memanfaatkan 'harta karun' yang ada dengan maksimal.

"Ya (bangun pabrik) di Indonesia. Kalau per sekarang dalam bayangan saja, nggak jangka pendek, adalah pabrik PLTS dari hulu, bukan nyambung-nyambung selnya diimpor. Kita ingin punya itu, industri yang hulunya, Pak Menteri ESDM juga sering menyampaikan," tambah Dadan.

Sebelumnya, Menteri Koordinator bidang Kemaritiman dan Investasi (Menko Marves) Luhut Binsar Pandjaitan mengungkapkan bahwa Singapura menginginkan adanya ekspor listrik Solar Panel dari Indonesia.

Namun, Luhut membeberkan bahwa Indonesia ingin proses pembuatan solar panel akan dilakukan sepenuhnya di dalam negeri. Luhut menjelaskan bahwa Indonesia ingin membangun industri dalam negeri mulai dari solar panel, baterainya, dan produk turunan selanjutnya, yang mana nantinya produk akhir baru akan diekspor.

"Mengenai mereka (Singapura) pingin ada ekspor solar panel dari Indonesia listriknya, dan Singapura. Tapi kita nggak mau begitu, maunya harus end to end. Kita harus bangun solar panel di sini, industrinya, kemudian baterainya, dan seterusnya. Baru kita ekspor ke Singapura jadi win-win," ungkapnya usai acara Indonesia Leading Economic Forum 2023, Jakarta, Selasa (14/3/2023).

Dengan demikian, lanjutnya, nantinya Indonesia akan mengekspor produk akhir, bukan hanya mengekspor bahan mentahnya saja.

Luhut menyebutkan investasi dalam membangun industri untuk solar panel bisa mencapai US$ 50 miliar atau setara dengan Rp 769,4 triliun (asumsi kurs Rp 15.389 per US$).

"Investasi seluruhnya nanti kalau kita lihat bisa potensi ke US$ 50 miliar," tambahnya.

Adapun, Sekretaris Jenderal Dewan Energi Nasional (DEN), Djoko Siswanto juga pernah mengungkapkan bahwa pihaknya serius dalam mendorong akselerasi penggunaan energi baru terbarukan, salah satunya terkait energi surya dengan pemanfaatan PLTS.

Namun untuk menggenjot pengembangan energi baru terbarukan itu tidak murah. Indonesia sendiri setidaknya butuh dana hingga Rp 4 triliun untuk membangun produksi panel surya.

"Saya bahkan pernah punya ide mengumpulkan BUMN menghadap menteri keuangan dan Kementerian Sekretariat Negara terkait kebutuhan dana Rp 4 triliun," jelasnya dalam Energy & Mining Outlook 2023, Kamis (23/2/2023).

OPINI: Catatan Atas Rancangan Undang-undang Energi Baru dan Terbarukan

Liputan6.com

Pengaturan terhadap aspek keekonomian di dalam RUU EBET diantaranya meliputi pengaturan harga dan mekanisme pembelian listrik EBET, pengaturan insentif, dan pembentukan Dana EBET.

Di dalam hal pengaturan harga dan mekanisme pembelian listrik EBET, RUU EBET tercatat menetapkan dua mekanisme penetapan harga jual listrik EBET, yaitu melalui kesepakatan para pihak dan melalui penetapan Pemerintah Pusat berupa harga patokan tertinggi.

Dalam hal penetapan harga pembelian melalui dua mekanisme di atas menemui kegagalan, maka dapat dilakukan penugasan oleh Pemerintah Pusat dengan harga yang ditetapkan melalui negosiasi para pihak.

Hal ini dilakukan dengan tetap mengacu pada harga keekonomian yang spesifik pada lokasi dan kapasitas yang akan dikembangkan sesuai dengan prosedur pengadaan yang berlaku.

Dalam hal ini, Pemerintah Pusat dapat menugaskan perusahaan listrik milik negara atau badan usaha milik swasta untuk membeli tenaga listrik yang dihasilkan dari EBET.

Di dalam kaitannya dengan pengaturan insentif, ketentuan yang diatur sejauh ini relatif masih bersifat umum. Pengaturan insentif di dalam RUU EBET mencakup pengaturan insentif dalam bentuk fiskal dan non-fiskal.

Insentif fiskal dalam hal ini dapat berupa insentif pajak penghasilan, pajak bumi dan bangunan, kepabeanan, penerimaan negara bukan pajak dan/atau keringanan iuran dan pungutan dalam berbagai bentuk.

Sementara insentif non-fiskal dalam hal ini dapat berupa kemudahan perizinan terkait pengadaan tanah dan infrastruktur serta pemanfaatan wilayah hutan.

Pengaturan lebih detail tentang insentif fiskal dan insentif non-fiskal disebutkan akan diatur dalam Peraturan Pemerintah. Dalam kaitan dengan aspek keekonomian, satu hal yang relatif baru dalam RUU EBET adalah adanya pengaturan tentang pembentukan Dana EBET.

Disebutkan Dana EBET dapat digunakan untuk pembiayaan infrastruktur EBET, pembiayaan insentif, kompensasi terhadap badan usaha yang mengembangkan EBET, penelitian dan peningkatan kapasitas sumber daya manusia.

Dana EBET dalam hal ini dapat bersumber dari APBN, APBD, pungutan ekspor energi fosil, perdagangan karbon dan sumber lain yang tidak bertentangan dengan peraturan perundang – undangan. Pengelolaan Dana EBET berada di bawah kewenangan Menteri Keuangan.

Dari sisi cakupan, pengaturan dan ketentuan yang berkaitan dengan aspek keekonomian di dalam RUU EBET pada dasarnya dapat diatakan sudah cukup lengkap. Namun, secara substansial pengaturan dan ketentuan tersebut pada dasarnya belum akan dapat secara langsung membuat mekanisme pasar di dalam investasi pengembangan EBET bekerja.

Dalam kaitannya dengan ketentuan harga jual listrik EBET misalnya, penetapan harga jual listrik EBET melalui mekanisme kesepakatan para pihak tetap belum sepenuhnya menjamin badan usaha pengembang listrik EBET dapat menjual listrik sesuai dengan harga keekonomian.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

mentara penetapan harga jual listrik EBET melalui penetapan Pemerintah Pusat berupa harga patokan tertinggi juga relatif belum memberikan jaminan kepada pengembang EBET bahwa listrik yang diproduksikannya akan terserap.

Sementara untuk pengaturan insentif untuk pengembangan EBET, sejauh ini ketidakpastian untuk terealisasikannya insentif tersebut masih cukup tinggi mengingat belum adanya aturan detail tentang skema dan mekanisme pemberian insentif tersebut.

Dengan kondisi tersebut, gambaran terhadap bagaimana kemungkinan pengaruh adanya pemberian insentif terhadap keekonomian pengembangan EBET menjadi relatif belum terukur. Kondisi yang sama juga berlaku untuk pengaturan Dana EBET, dimana implementasi Dana EBET masih akan bergantung dan ditentukan oleh pengaturan di tingkat aturan pelaksananya.

Catatan akhir

Dari sisi praktis, dalam pengertian bagaimana agar pengembangan EBET dapat segera terealisasi dengan konkret, dari berbagai aspek yang ada, aspek keekonomian dapat dikatakan merupakan aspek vital yang terpenting.

Dalam konteks ini, di dalam proses legislasi dan pembahasan RUU EBET yang masih akan terus berjalan penyempurnaan di dalam operasionalisasi aspek keekonomian kiranya perlu dilakukan.

Di dalam aspek keekonomian, RUU EBET perlu lebih diarahkan untuk dapat secara lebih spesifik mengatur dan memuat ketentuan-ketentuan yang secara praktis dapat memfasilitasi, memberi kepastian, dan menjamin berjalan dan bekerjanya mekanisme pasar di dalam investasi-investasi EBET secara efektif,, efisien dan sehat.

Sebagai contoh dalam hal ini adalah pengaturan di dalam penerapan harga listrik EBET maupun skema *Feed In Tariff (FIT*) yang menyertainya.

Hendaknya di dalam pengaturan harga dan skema *FIT* ini RUU EBET nantinya tidak sekadar menetapkan rentang skala harga dan FIT yang layak saja, tetapi juga mengatur secara lebih lugas bahwa pemerintah melalui mekanisme insentif ataupun subsidi tertentu adalah pihak yang akan menanggung selisih keekonomian investasi yang tidak dapat dicapai melalui mekanisme pasar murni.

Pengalaman di berbagai negara mengajarkan bahwa keekonomian di dalam sebagian besar investasi EBET memang memerlukan pengaturan cukup detail dan intervensi langsung dalam bentuk insentif baik fiskal maupun non-fiskal dari pemerintah.

Termasuk di dalam hal ini misalnya adalah kejelasan pengaturan dalam hal kewajiban atau penugasan kepada pihak tertentu untuk membeli listrik yang dihasilkan dari pembangkit EBET dan atau di dalam menanggung selisih harganya yang mungkin masih di bawah nilai keekonomian.

Tanpa kejelasan tentang siapa pihak yang akan menanggung selisih keekonomian itu, dalam apa bentuknya, dan melalui mekanisme apa, sulit untuk mengharapkan investasi EBET akan dapat berjalan, apalagi dalam skala masif.

Kejelasan di dalam aspek keekonomian dari RUU EBET dapat dikatakan merupakan penentu keberhasilan dalam pelaksanaan transisi energi maupun di dalam pengembangan EBET secara lebih luas di tanah air.

ENERGI TERBARUKAN

Pemanfaatan Energi Surya di Indonesia Masih Sulit Berkembang

Berdasarkan data Ditjen EBTKE Kementerian ESDM, realisasi kapasitas terpasang PLTS pada 2022 ialah 271,6 MW atau jauh di bawah rencana 893,3 MW. Saat ini peraturan menteri terkait PLTS atap tengah direvisi.

Audio Berita 6 menit

KOMPAS/RONY ARIYANTO NUGROHO

Pembangkit listrik tenaga surya.

JAKARTA, KOMPAS — Pembangkit listrik tenaga surya atau PLTS di Indonesia masih sulit berkembang meskipun berpotensi menjadi penopang untuk memacu energi terbarukan dalam bauran energi primer. Salah satu kendalanya adalah masih ada sejumlah batasan dalam kapasitas terpasang PLTS ak[illegible]nsokan daya listrik yang

Baca di Aplikasi

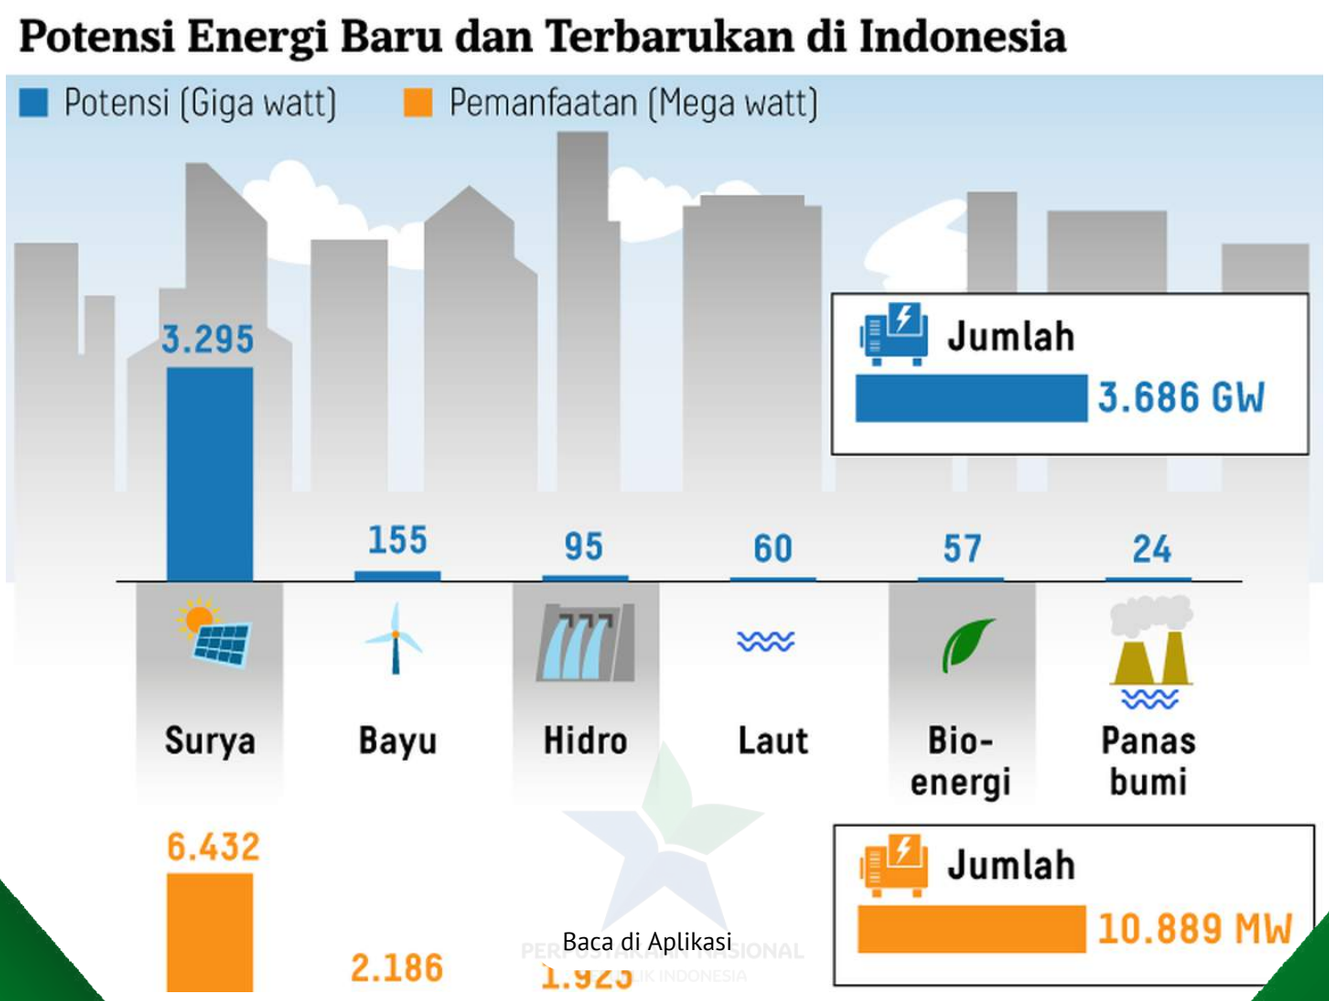
Ketua Asosiasi Pabrikan Modul Surya Indonesia (Apamsi) Linus Andor Mulana Sijabat, saat dihubungi Kamis (23/3/2023), mengatakan, ada sebanyak 12 produsen modul surya yang tergabung dalam Apamsi. Namun, semuanya berhenti beroperasi karena tidak ada pasar atau permintaan untuk panel surya tersebut.

Linus menjelaskan, pasar panel surya Indonesia itu untuk produsen listrik swasta (*independent power producer*/IPP) atau PLTS atap. Namun, semua itu bergantung pada PLN. Kendati Kementerian Energi dan Sumber Daya Mineral (ESDM) telah menerbitkan sejumlah aturan untuk percepatan PLTS, akhirnya tak bisa dijalankan PLN.

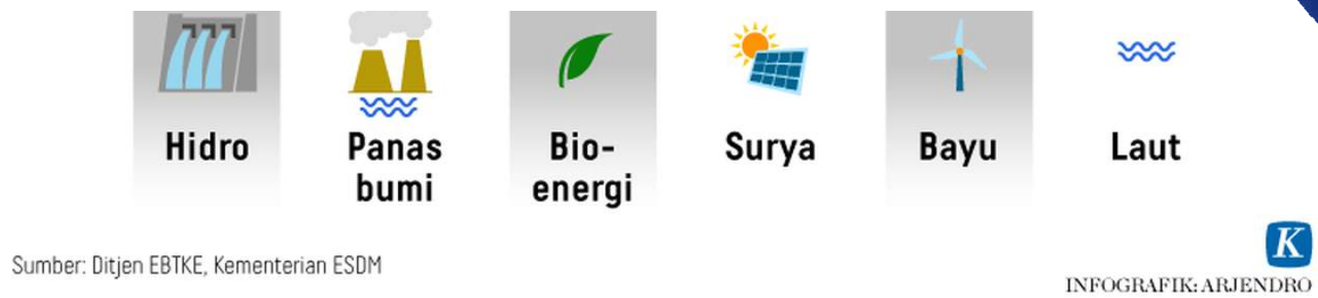
Baca juga: Pemasangan Panel Surya Atap Masih Terkendala

”Yang ditargetkan tidak terjadi sehingga *market*-nya tidak tumbuh. Sebanyak 12 perusahaan ini stop beroperasi. Waktu itu, konsisten hanya pada 2015 dan sesudah itu tidak ada lagi. Tentu yang diharapkan (agar PLTS tumbuh dan berkembang) ialah konsistensi PLN (menjalankan) regulasi yang ada,” kata Linus.

Di sisi lain, imbuh Linus, PLTS, termasuk PLTS atap, sebenarnya paling memungkinkan untuk memacu capaian energi terbarukan di Indonesia. Sebab, pembangkit listrik tenaga air (PLTA) memerlukan waktu lama dalam pembangunannya. Begitu juga pada pembangkit listrk tenaga panas bumi (PLTP).



Baca di Aplikasi



Sebelumnya, dalam pameran Solartech Indonesia, di JIExpo, Jakarta, awal Maret 2023, sejumlah perusahaan penyedia sistem panel surya mengatakan, saat ini nyaris semua panel surya yang terpasang di Indonesia ialah produk impor. Produsen panel surya skala besar didominasi produk-produk buatan luar negeri.

Sementara terkait permintaan pemasangan, ada kecenderungan tumbuh sejak 2019. "Namun, adanya pembatasan kapasitas terpasang (PLTS atap) 15 persen, sejak 2022 membuatnya menurun hingga 50 persen. Terutama pada pelanggan untuk hunian," kata Sales Engineer Sedayu Solar, Ilham Setiawan.

Berdasarkan data Direktorat Jenderal Energi Baru, Terbarukan, dan Konservasi Energi (EBTKE) Kementerian ESDM, realisasi kapasitas terpasang PLTS pada 2022 ialah 271,6 megawatt (MW) atau jauh di bawah rencana sebesar 893,3 MW. Hanya ada penambahan 66,9 MW dari 2021 yang kapasitas terpasangnya 204,7 MW. Sebelumnya, Kementerian ESDM menargetkan 3.600 MW kapasitas terpasang PLTS atap pada 2025.

Relaksasi

Dalam diskusi terkait sinergi nasional untuk mencapai target kontribusi nasional untuk penurunan emisi (*nationally determined contribution*/NDC) 2030 dan emisi nol bersih (NZE) 2060 yang digelar Masyarakat Ketenagalistrikan Indonesia (MKI) secara hibrida, Rabu (21/3/2023), lambatnya pertumbuhan PLTS juga menjadi salah satu poin yang dibahas.

Wakil Ketua Masyarakat Energi Terbarukan Indonesia (METI) Andhika Prastawa, dalam diskusi itu, mengatakan, PLTS atap ialah jenis energi terbarukan dengan teknologi dan bisnis yang mendasar dan mudah. Namun, perkembangannya sangat lambat dan membutuhkan lagi intervensi.

Baca di Aplikasi

PUTU FAJAR ARCANA

Instalasi panel surya di Kampung Malahing sebagai sumber energi yang sudah tidak berfungsi lagi.

Menurut dia, bicara target transisi energi, seharusnya tidak hanya bicara level makro, tetapi juga meso dan mikro.

”Sebab, di situlah *enabling* bekerja. Contohnya, kita bisa membuat kebijakan relaksasi agar (PLTS) *rooftop* (atap) tumbuh, dipermudah. Memang, kalau tak dijaga akan menjadi ekses (kelebihan daya). Namun, peraturan tidak tabu untuk diubah setelah target terpenuhi. Jadi, tetap dijaga,” kata Andhika.

Executive Vice President Perencanaan Sistem Ketenagalistrikan PLN Warsono mengatakan, Kementerian ESDM akan membuat aturan baru yang mendukung pengembangan PLTS atap. Pihaknya pun akan mendukung kebijakan tersebut.

Baca juga: Kuota PLTS Atap Perlu Dihitung Cermat

”Salah satunya adalah dengan *metering* di sisi pelanggan sehingga nantinya bisa diagregat, berapa kWh (kilowatt jam) di *rooftop* ini. Ini yang selama ini barangkali belum teragregat. Nantinya, berapa kontribusi terhadap EBT (energi baru terbarukan) akan bisa dihitung perkembangannya dari waktu ke waktu,” ujarnya.

Sebelumnya, dalam rapat dengar pendapat dengan Komisi VI DPR RI pada 28 November 2022, Direktur Utama PLN Darmawan Prasodjo menuturkan, PLN sedang mengalami kelebihan pasokan daya listrik (*oversupply*). Pihaknya mendukung penuh pengembangan energi terbarukan. Namun, selama masih *oversupply*, titik tengahnya ialah agar pemasangan PLTS atap sesuai dengan kapasitas konsumsi pelanggan (Kompas.id, 13/1/2023).

Saat ini, Kementerian ESDM sedang dalam proses merevisi Peraturan Menteri ESDM Nomor 26 Tahun 2021 tentang PLTS Atap yang

Baca di Aplikasi

dalam rangka percepatan implementasi PLTS atap serta memberi kesempatan lebih luas bagi masyarakat dalam memasangnya.

KOMPAS/WAWAN H PRABOWO (WAK)

Deretan kincir angin Pembangkit Listrik Tenaga Bayu (PLTB) menghiasi puncak bukit di Dusun Tanarara, Desa Maubokul, Kecamatan Pandawai, Sumba Timur, Nusa Tenggara Timur, Rabu (3/2/2021). Sebagian besar dari 48 kincir angin yang dibangun pada 2013 lalu itu hingga kini masih berfungsi dengan baik dalam memenuhi kebutuhan listrik masyarakat sekitar.

JAKARTA, KOMPAS — Pemerintah memberikan sejumlah insentif kepada badan usaha dalam pengembangan energi terbarukan di Indonesia. Insentif yang tertuang dalam [illegible] tersebut diharapkan dapat

Baca di Aplikasi

petunjuk teknis dari aturan tersebut.

Aturan yang dimaksud adalah Peraturan Presiden (Perpres) Nomor 112 Tahun 2022 tentang Percepatan Pengembangan Energi Terbarukan untuk Penyediaan Tenaga Listrik. Perpres tersebut diundangkan pada 13 September 2022. Ketentuan mengenai insentif tertuang dalam Bab V tentang Dukungan Pemerintah pada Pasal 22. Insentif yang diberikan pemerintah dalam bentuk fiskal dan nonfiskal.

Insentif fiskal yang dimaksud adalah pembebasan bea masuk impor, fasilitas pembiayaan lewat penjaminan melalui BUMN yang ditugaskan negara, dan fasilitas perpajakan. Sementara fasilitas nonfiskal dalam Pasal 22 tersebut diberikan oleh pemerintah pusat dan pemerintah daerah sesuai aturan yang berlaku. Salah satu bentuk dukungan, baik di pusat maupun daerah, adalah agar perizinan pengembangan energi terbarukan dipermudah.

Direktur Eksekutif ReforMiner Institute Komaidi Notonegoro saat dihubungi, Kamis (15/9/2022), di Jakarta, mengatakan, terbitnya Perpres tersebut menjadi hal yang sangat baik. Saat ini yang utama adalah perihal implementasinya.

Baca juga: Industri Memainkan Peranan Penting dalam Transisi Energi

Ia mengatakan, intervensi dari pemerintah atau subsidi akan tetap diperlukan. Mekanisme yang diambil pemerintah untuk menutup hal tersebut bisa bermacam-macam, salah satunya pengurangan pajak bagi PT Perusahaan Listrik Negara (Persero). Dengan demikian, pemerintah tidak harus mengeluarkan langsung dari APBN. "Kalau tidak ada intervensi, tidak akan jalan," ucapnya.

Beberapa Poin Penting dalam Peraturan Presiden Nomor 112 Tahun 2022

Bab II tentang Harga Pembelian Tenaga Listrik

Pasal 5 Ayat (1) Harga pembelian tenaga listrik dari pembangkit tenaga listrik yang memanfaatkan sumber energi terbarukan oleh PT PLN (Persero) sebagai dimaksud dalam Pasal 4 Ayat (2) terdiri atas:

a. Harga patokan tertinggi sebagaimana tercantum dalam lampiran I yang merupakan bagian tidak terpisah dari peraturan presiden ini; atau

b. Harga kesepakatan, dengan atau tanpa memperhitungkan faktor lokasi (F).

Sumber: Peraturan Presiden Republik Indonesia Nomor 112 Tahun 2022 tentang Percepatan Pengembangan Energi Terbarukan untuk Penyediaan Tenaga Listrik

INFOGRAFIK: HANS

Meski membawa harapan dan sebagai pintu masuk, lanjut Komaidi, implementasi tidak akan sederhana karena dibutuhkan aturan turunan dan petunjuk teknisnya. Oleh karena itu, implementasi dari perpres perlu dipastikan.

Wakil Ketua Komisi VII DPR dari Fraksi Partai Amanat Nasional Eddy Soeparno menambahkan, payung hukum merupakan salah satu bentuk dukungan pemerintah terhadap pengembangan energi terbarukan di Indonesia. Selain itu, diperlukan juga insentif agar akselerasi dapat terwujud.

”Pasalnya, Indonesia memiliki dua target, yakni bauran energi terbarukan 23 persen pada 2025 dan melepaskan ketergantungan dari energi berbasis fosil. Biaya pengembangan energi terbarukan membutuhkan biaya yang tinggi, terlebih terkait pengembangan infrastrukturnya, sehingga akan berdampak pada harga jual listrik. Implementasi insentif ini penting,” kata Eddy.

KOMPAS/TOTOK WIJAYANTO (TOK)

Petugas membersihkan panel surya Pembangkit Listrik Tenaga Surya (PLTS) di atas atap pabrik terigu milik PT Indofood Sukses Makmur Tbk Divisi Bogasari, Cibitung, Bekasi, Jawa Barat, Jumat (9/9/2022). PLTS yang baru mulai dioperasikan itu mempunyai kapasitas sebesar 1 megawatt-peak dan digunakan untuk memenuhi kebutuhan listrik pabrik tersebut.

Ruang negosiasi

Anggota Komisi VII DPR dari Fraksi Partai Keadilan Sejahtera, Rofik Hananto, menambahkan, yang menjadi kendala selama ini tidak hanya soal harga, tetapi juga proses tender dan negosiasi harga. Dengan penetapan harga batas atas, masih ada ruang negosiasi antara PLN dan pengembang energi terbarukan. Biasanya, dari yang sudah-sudah, negosiasi berlangsung lama. Beda halnya jika, misalnya, harga telah ditetapkan (fixed).

Ia menambahkan, soal tender ada perbedaan di antara jenis energi terbarukan yang satu dan lain, misalnya pada solar (panel surya) yang relatif tak memerlukan studi awal besar, sementara lainnya berbeda. ”Aspek-aspek teknis harus diperhatikan dalam mengimplementasikan perpres ini jika ingin mempercepat pengembangan energi terbarukan,” ucapnya.

Pelaksana Tugas Direktur Jenderal Ketenagalistrikan Kementerian Energi dan Sumber Daya Mineral (ESDM) Dadan Kusdiana, saat dikonfirmasi terkait upaya pemerintah agar implementasi Perpres No 112/2022 berjalan, hingga Kamis malam, belum merespons.

Sementara itu, Felix Frederi[illegible]agian Business

pengembangan listrik panas bumi, di sela-sela International Geothermal Convention & Exhibition (IIGCE) di Jakarta, Kamis, menyambut positif terbitnya perpres tersebut.

Selama ini pengembangan lebih banyak di wilayah timur Indonesia yang secara keekonomian lebih menguntungkan. ”Sekarang, sederhananya disetarakan dan bisa memberi ruang eksplorasi bagi kami, terutama untuk Sumatera yang memiliki banyak sumber panas bumi. Sebelumnya kami lebih fokus di timur,” ujarnya.

Penyimpanan Energi, Kunci Menuju Integrasi Energi Terbarukan di Indonesia - Koran-Jakarta.com

Koran Jakarta

Ahmad Amiruddin, *Monash University*

Meski sempat tersendat karena pandemik COVID-19, pertumbuhan listrik di Indonesia diprediksi tetap akan naik dalam 10 tahun terakhir pada angka 4,9% sesuai dengan Rencana Usaha Penyediaan Tenaga Listrik (RUPTL) Perusahaan Listrik Negara (PLN) 2021-2030.

Selain harus memenuhi kebutuhan listrik yang meningkat, Indonesia juga dihadapkan pada target pencapaian porsi energi terbarukan 23% pada 2025 dalam Rencana Umum Ketenagalistrikan (RUKN) 2019-2038. Saat ini capaiannya masih pada kisaran 11,2%.

Kabar baiknya adalah potensi energi terbarukan yang kita miliki lebih dari cukup untuk memenuhi kebutuhan pengembangan energi terbarukan bahkan hingga 100% pada tahun 2050.

Masalahnya, pembangunan pembangkit energi terbarukan khususnya yang berbasis angin dan surya, tidak serta merta menyelesaikan target penetrasi energi terbarukan. Sebab, dua jenis energi ini sifatnya variatif dan pasokannya tak menentu.

Hasil wawancara saya dengan PLN pada 2017 terkait operasional Pembangkit Listrik Tenaga Bayu (PLTB) Sidrap, Sulawesi Selatan, menunjukkan bahwa terdapat perbedaan rata-rata hingga 74%, bahkan ada yang mencapai 1027%, antara prediksi dan realisasi produksi dari PLTB. Sebuah gap yang sangat besar.

Kuncinya: Penyimpanan Energi

Agar kapasitas listrik dari energi terbarukan bertambah, Indonesia membutuhkan sistem kelistrikan andal dan fleksibel untuk mengikuti perubahan pasokan sekaligus mengantisipasi perubahan beban.

Selain dihadapkan pada keharusan meningkatkan fleksibilitas untuk dapat menyerap energi terbarukan, sistem kelistrikan di Jawa-Bali juga cukup rentan terhadap gangguan besar. Misalnya kejadian pemadaman mendadak di Jawa bagian barat pada 4 Agustus 2019.

Untuk meningkatkan fleksibilitas dan keandalan sistem kelistrikan, maka pilihan yang paling masuk akal adalah fasilitas baterai energi atau disebut juga *energy storage*. Baterai ini juga dapat bekerja sebagai pembangkit awal (*black start*) saat pemadaman listrik mendadak seperti pada kasus di Jakarta. Fungsi lainnya adalah mencegah mati listrik dengan mendukung sistem dalam periode genting sebelum padam total.

Baterai energi ini telah digunakan di banyak negara termasuk Amerika Serikat, Australia, Inggris, Jerman, Korea, Jepang, Cina, dan Thailand. Satu studi menunjukkan bahwa *energy storage* di Australia berhasil mencegah terjadinya listrik padam mendadak pada 25 Agustus 2018.

Studi lainnya menunjukkan bahwa penyimpanan energi di Australia dapat menurunkan biaya produksi listrik hingga 13-22%, mengurangi kapasitas pembangkit hingga 22%, dan mencegah energi yang terbuang hingga 76%.

Indonesia saat ini belum memiliki *energy storage*. Proyek fasilitas penyimpanan energi pertama yang berlokasi di Cisokan, Bandung Barat, masih dalam masa pembangunan. *Energy storage* yang dapat digunakan bisa menyesuaikan dengan potensi alam, potensi bahan baku, dan karakteristik yang saling melengkapi.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

si penyimpan energi ini antara lain Pembangkit Listrik Tenaga Air (PLTA) teknologi *pumped storage* atau PHS, baterai lithium-ion (*Lithium-Ion battery*. LIB), dan baterai dinamis (*Redox Flow Battery*,RFB).

PLTA Pumped-Storage

PLTA pumped-storage (PHS) adalah teknologi *energy storage* paling tua dan paling banyak proporsinya sekarang ini. Tercatat 96% dari 176 GW penyimpanan energi secara global pada 2017 adalah jenis ini.

Penyimpan energi ini memiliki karakteristik yang mirip dengan PLTA biasa, dan dapat merespons kebutuhan pembangkitan listrik yang cepat - dalam hitungan menit. Efisiensinya mencapai 70-80%, dengan kapasitas yang cukup besar, dari 1.000-15.000 MW.

Indonesia sendiri memiliki potensi lokasi yang dapat digunakan sebagai *pumped-storage*. Sebuah studi pada 2019 menghitung potensi *pumped-storage* di Indonesia dapat mencapai 871 TWh di 26.000 lokasi. Namun hipotesis ini perlu penelitian lebih lanjut mengingat pembangunan *pumped-storage* tidak selamanya mudah.

Indonesia berencana membangun beberapa *pumped storage* dalam 10 tahun ke depan. Perencanaan dan pembangunan *pumped-storage* Cisokan, Bandung Barat, kapasitas 1.040 MW di Indonesia telah dimulai pada 2010. Awalnya proyek ini akan ditargetkan beroperasi pada 2014, namun mengalami berbagai kendala.

Dalam rencana terbaru baru penyimpanan energi ini akan beroperasi pada 2025. Artinya terjadi kemunduran paling tidak 11 tahun dari perencanaan awal. Adapun *pumped storage* lainnya masih tahap perencanaan.

Karena itu saya juga mengusulkan alternatif penyimpanan energi yang lebih cepat pembangunannya, kepadatan energi yang tinggi, tidak tergantung lokasi dan pertimbangan biaya. Jenis tersebut adalah baterai litium-ion (*Lithium-Ion battery*) dan baterai dinamis (*Redox Flow Battery*).

Baterai Lithium-ion

Baterai litium-ion telah menjadi bagian integral dari perkembangan industri elektronik dan telepon seluler. Baterai ini juga pendorong utama perkembangan kendaraan listrik.

Pada masa depan baterai ini dianggap sebagai lokomotif dan kunci dari energi yang berkelanjutan sebagai media penyimpan dengan kepadatan energi yang tinggi. Harganya pun terus menurun secara signifikan dari tahun ke tahun hingga 89% dalam 10 tahun terakhir.

Kekurangan utama dari baterai ini adalah biaya instalasi yang relatif tinggi. Persyaratan sistem manajemen baterai juga ketat. Ada pula kekhawatiran terjadi kebakaran yang dipicu reaksi internal dari baterai.

Sebagai pengekspor nikel terbesar di dunia, Indonesia baru memulai pendirian [Indonesia Battery Corporation (IBC)] pada Maret 2021. Indonesia memiliki peluang untuk mengembangkan baterai ini dengan mengarahkan pasarnya tidak hanya menyasar kendaraan listrik tapi untuk penyimpanan energi.

Menurut rencana PLN 2021-2030, selain *pumped storage* akan dibangun juga jenis baterai lain dengan kapasitas 300 MW pada 2030. Jenis teknologi baterai yang akan dibangun belum ditentukan, tapi baterai litium-ion adalah pilihan yang perlu diprioritaskan.

Redox Flow Battery (RFB)

FB adalah alternatif lain jenis penyimpanan energi yang juga dapat dikembangkan.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

terai ini cocok untuk penggunaan yang sifatnya tak bergerak, sehingga lebih aplikatif untuk penyimpanan energi dibanding penggunaan untuk baterai yang bergerak (untuk telepon seluler, laptop atau kendaraan listrik) yang menjadi kelebihan dari baterai litium-ion.

Tak seperti baterai konvensional yang menggunakan material elektroda untuk menyimpan energi, RFB memakai cairan elektrolit yang disuplai dari tangki sebagai media penyimpanan. Konstruksi dari baterai ini memerlukan pompa dan tangki untuk menyimpan elektolit.

Pengontrolan daya dan energinya dapat terpisah. Untuk mengontrol energinya dengan menambahkan volume tangki, sementara untuk daya dilakukan dengan mengontrol aliran elektrolit.

Untuk dapat meningkatkan penetrasi energi terbarukan di Indonesia, pemerintah perlu melakukan langkah pendukung yang memungkinkan agar energi terbarukan dapat terintegrasi dengan mulus dengan sistem kelistrikan.

Penyimpanan energi menjadi pilihan prioritas mengingat karakteristiknya yang luas. Pilihan penyimpanan energi yang banyak dan dapat disesuaikan dengan kebutuhan sistem kelistrikan di Indonesia.

Pertamina Buka Kompetisi Program PFsains | SWA.co.id

Silawati

Kompetisi PFsains 2023 bertema “Inovasi Energi Terbarukan untuk Mendukung Kemandirian Ekonomi Masyarakat”. (Foto: Pertamina)

Untuk mendukung target nol emisi karbon dan bauran energi baru dan terbarukan, Pertamina melalui Pertamina Foundation membuka pendaftaran kompetisi PFsains 2023 bertema “Inovasi Energi Terbarukan untuk Mendukung Kemandirian Ekonomi Masyarakat”. PFsains mengajak mahasiwa/praktisi/maupun akademisi untuk mengembangkan proyek inovasi energi terbarukan mereka bersama Pertamina.

Program PFsains merupakan salah satu dari 5 (lima) program unggulan PFseries Pertamina Foundation dan menjadi ajang kompetisi karya ilmiah hasil penelitian atau praktik-praktik pengembangan energi ramah lingkungan. Tahun ini, PFsains hadir dengan dua kategori yang bisa diikuti, yaitu Ideation dan Implementation. Kategori Ideation merupakan kategori hasil penelitian berupa laporan akhir yang punya potensi untuk diimplementasikan. Sementara Implementation bisa diikuti oleh peserta yang hasil penelitiannya sudah memiliki lokasi dan siap untuk diimplementasikan dalam waktu dekat.

Executive Advisor to Director Pertamina New & Renewable Energy (PNRE) Nareswari Sumarsono mengatakan misi PFsains sejalan dengan PNRE dan mampu mendorong inovator EBT. “PFsains ini sejalan dengan misi PNRE yaitu mendorong sekaligus mengembangkan potensi energi baru terbarukan Indonesia. Untuk itu, saya mendukung kehadiran PFsains karena saya yakin di Indonesia banyak ide-ide menarik dan inovatif yang membutuhkan wadah untuk diimplementasikan".

Proposal terbaik PFsains akan mendapatkan total pendanaan proyek hingga miliaran rupiah. Tidak hanya pendanaan, pemenang PFsains akan mendapatkan coaching dan mentoring dari Research and Technology Innovation Pertamina, Pertamina New Ventures, PERTIWI, dan lembaga terkait EBT lainnya.

“Bersama Pertamina Foundation, Pertamina New Ventures akan memberikan ruang untuk para inovator yang punya ide, kreasi, dan inovasi guna menjamin sustainability energy di Indonesia. Dari New Ventures akan menyambut yang terbaik untuk dikomersialisasikan,” ungkap Vice President Pertamina New Ventures Indira Pratyaksa.

nfaat lainnya adalah matchmaking fund, di mana mempertemukan pemenang dengan pendonor

n dan potensi replikasi inovasi energi dari Pertamina Grup. Branding dan publikasi melalui website, media massa, dan media sosial juga akan diperoleh pemenang PFsains.

”PFsains menjadi bentuk dukungan terhadap komitmen Pertamina dalam transisi energi dan dekarbonisasi. Pada program ini, kami mencari riset dan proyek inovasi energi yang mampu menyelesaikan permasalahan energi masyarakat sekitar, bersifat berkelanjutan dan membawa kemandirian serta mengedepankan HSSE (Health, Safety, Security and Environment). PFsains menggandeng Pertamina Grup untuk nantinya inovasi mereka tidak hanya dikembangkan tapi juga dikomersialisasikan,” ujar Presiden Direktur Pertamina Foundation Agus Mashud S. Asngari

Selama tiga tahun berjalan, program PFsains telah menghadirkan 20 proyek pengembangan Energi Baru Terbarukan (EBT) dengan variasi inovasi, mulai dari pembangkit listrik tenaga surya (PLTS), pembangkit listrik tenaga bayu (PLTB), pembangkit listrik arus laut (PLTAL), serta hybrid. Total proyek inovasi PFsains telah menghasilkan energi dari PLTS sebesar 31.200 watt-peak, hybrid 3.200 watt-peak, dan menerangi lebih dari 700 kepala keluarga.

PLTS Atap, Indonesia Perlu Belajar dari Pergulatan Vietnam

Farid Firdaus, Farid Firdaus

Bisnis.com, JAKARTA - Implementasi suplai listrik dari pembangkit listrik tenaga surya (PLTS) Atap masih mengalami sejumlah hambatan. Indonesia dinilai perlu berlajar dari pergulatan Vietnam menghadapi kendala serupa.

Pengamat Kebijakan Publik Agus Pambagio mengatakan kesiapan Indonesia dalam implementasi PLTS Atap, tergantung peran para pelaku usahanya. Ia berkesimpulan saat ini Indonesia belum siap terkait dengan implementasi PLTS Atap.

“Pengembangan PLTS Atap ini kan juga belum jelas strateginya antara yang *solar sell*, di atas atap, atau secara luas. Kemudian juga belum berbicara *mau off grid* atau *on grid*,” jelasnya di sela-sela diskusi publik di Jakarta, Selasa (21/3/2023).

Diskusi bertajuk *Energi Surya Indonesia, Mau Dibawa Kemana?* itu membahas soal pengembangan EBT sebagai sumber energi listrik dan ketersediaan infrastruktur kelistrikan yang memiliki peranan penting dan sangat krusial. Saat ini peningkatan bauran energi baru terbarukan khususnya melalui PLTS Atap ini masih menghadapi persoalan yang cukup fundamental.

Menurut Agus, Vietnam sebagai salah satu negara di Asia Tenggara yang gencar memakai PLTS atap akhirnya tumbang karena regulasinya sendiri.

Diketahui, selama kurun waktu 1 tahun yaitu periode 2019–2020, terjadi penambahan kapasitas hampir 8 GW untuk PV Rooftop dan hampir 8 GW untuk solar farm. Namun, hal tersebut meninggalkan persoalan baru bagi sistem kelistrikan Vietnam, di mana akhirnya pelanggan, investor dan Vietnam Electricity/EVN selaku *offtaker* harus menanggung pil pahit itu.

Maju Mundur Pengembang Properti Terapkan PLTS Atap di Proyek Residensial

Sektor Komersial dan Industrial Mulai Lirik PLTS Atap

Intermintensi atau ketidakandalan cuaca diakui menjadi salah satu kelemahan pembangkitan listrik dari tenaga surya karena pemasang/pengusaha PLTS tidak bisa mengatur iradiasi matahari.

Intermitensi sebenarnya menggambarkan terputus-putusnya produksi listrik pembangkit listrik surya maupun angin yang sangat bergantung pada faktor cuaca. Dengan demikian, kondisi ini mengganggu keandalan listrik sehingga kualitas layanan jadi tidak maksimal.

“Masih banyak kendala terkait dengan implementasinya,” kata Erlangga Bayu dari perwakilan Asosiasi Pembangkit Surya Atap di Bali.

Kendala tersebut, paparnya, juga terkait dengan sejumlah kebijakan, baik di daerah maupun tingkat nasional. Saat ini diketahui, masih dilakukan harmonisasi atas kebijakan tersebut karena dianggap belum matang bagi pemerintah dan pengusaha.

Saat ini, Kementerian Energi dan Sumber Daya Mineral (ESDM) tengah merampungkan revisi Peraturan Menteri (Permen) ESDM Nomor 26 tahun 2021 tentang Sistem PLTS Atap yang Terhubung Dengan Jaringan Pemegang IUPTLU.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

visi itu diharapkan dapat menjadi jalan tengah antara kepentingan PLN dengan industri dan masyarakat yang berinisiatif untuk meningkatkan pemasangan panel surya mendatang.

roduksi Energi Terbarukan di Seluruh Dunia Meningkat Signifikan pada 2022

AFP

Produksi energi terbarukan mengalami peningkatan yang belum pernah terjadi sebelumnya pada tahun 2022 hingga hampir 10 persen di seluruh dunia, ungkap Badan Energi Terbarukan Internasional pada Selasa (21/3). Meski demikian, lembaga itu memperingatkan bahwa angka itu belum cukup untuk membatasi perubahan iklim.

Tahun lalu, 83 persen kapasitas pembangkit listrik baru berasal dari sumber terbarukan, kata badan IRENA saat mengumumkan peningkatan kapasitas energi terbarukan sebesar 9,6 persen secara global.

Tenaga surya, terutama fotovoltaik, dan angin masih menyumbang 90 persen dari konstruksi baru tersebut. Meski lembaga itu mencatat perlambatan sektor angin jika dibandingkan dengan dua tahun sebelumnya, kapasitas produksi tenaga angin masih tetap meningkat sebesar 9 persen, sementara tenaga surya naik sebesar 22 persen.

Pembangkit listrik tenaga air masih menjadi sumber terbesar sektor itu, terhitung mencapai 37 persen dari total kapasitas dan menghasilkan 1.256 gigawatt, menurut laporan Renewable Capacity Statistics 2023.

Total kapasitas produksi listrik, termasuk dari seluruh sumber energi terbarukan, mencapai 3.372 GW pada akhir tahun 2022.

“Berlanjutnya pertumbuhan yang mencapai rekor ini menunjukkan ketahanan energi terbarukan,” kata direktur jenderal IRENA, Francesco La Camera.

“Namun penambahan kapasitas energi terbarukkan tahunan harus tumbuh tiga kali lipat dari tingkat saat ini pada 2030 nanti, jika kita ingin tetap berada pada jalur untuk dapat membatasi pemanasan global hingga 1,5 derajat Celcius,” ungkapnya.

“Karena permintaan energi diperkirakan akan meningkat di banyak wilayah di dunia, transisi energi membutuhkan langkah perubahan yang memberikan perubahan strategis di luar dekarbonisasi sisi pasokan,” katanya.

Asia menjadi wilayah geografis yang mengalami pertumbuhan fasilitas energi terbarukan terbesar tahun lalu.

China menjadi kontributor utama, dengan kapasitas energi terbarukan baru sebesar 141 GW, hampir separuh dari total kapasitas baru sebesar 295 GW secara global.

Eropa dan Amerika Utara masing-masing naik 57,3 GW dan 29,1 GW.

Di Afrika, peningkatan itu mencapai 2,7 GW.

Sementara Timur Tengah mengalami peningkatan produksi listrik baru sebesar 3,2 GW, dengan peningkatan yang memecahkan rekor di kawasan, yaitu sebesar 12,8 persen. *[rd/jm]*

INDUSTRI / ENERGI

Ramai-Ramai Mencuil Peluang Bisnis di Energi Baru Terbarukan

Minggu, 19 Maret 2023 / 21:38 WIB

INDEKS BERITA

Adaro Power mengoperasikan Pembangkit Listrik Tenaga Surya (PLTS) atap dan terapung di area operasional pelabuhan/terminal khusus batubara Adaro di Kelanis, Kalimantan Tengah.

Reporter: **Muhammad Julian** | Editor: **Noverius Laoli**

KONTAN.CO.ID - JAKARTA. Grup Adaro memperkuat portofolio bisnis di bidang energi terbarukan. Lewat PT Adaro Clean Energy Indonesia (Adaro Green), Grup Adaro berencana membangun pembangkit listrik tenaga surya (PLTS) di Provinsi Kepulauan Riau.

Presiden Direktur PT Adaro Power, Dharma Djojonegoro mengatakan bahwa PLTS tersebut akan digunakan untuk memenuhi kebutuhan energi baru dan terbarukan (EBT) di dalam negeri dan kawasan regional.

Pada akhirnya, Adaro akan menjadi *independent power producer* (IPP) dengan PLTS tersebut. Dharma tidak merinci jadwal proyek atau jumlah kapasitas PLTS yang direncanakan terpasang.

"Sesuai arahan pemerintah, kami akan menggunakan permintaan yang tinggi dari Singapura untuk EBT yang tidak intermiten dengan me industri rantai pasok solar PV," kata Dharma kepada Kontan.co.id Minggu (19/3).

Baca Juga: **Anak Usaha TOBA, PT Energi Baru TBS Tandatangani M Pengembangan Energi Terbarukan**

Saat ini, pemerintah sedang menjalin kerja sama dengan Pemerinta Singapura untuk mengembangkan EBT. Upaya ini telah membuahka penandatanganan nota kesepahaman antara Kementerian Koordinator dang Kemaritiman dan Investasi (Kemenko Marves) dengan Kantor ana Menteri Singapura.

PERPUSTAKAAN NASIONAL
REPUBLIK INDONESIA

...ota kesepahaman tersebut mencakup kerja sama investasi pengembangan industri dan kapabilitas manufaktur EBT di Indonesia dari hulu ke hilir, serta perdagangan listrik lintas batas antara kedua negara.

Adaro Green, PT Medco Power Indonesia (Medco Power), dan PT Energi Baru TBS (Energi Baru) juga telah menandatangani nota kesepahaman pengembangan energi terbarukan (EBT) serta rantai pasok Solar Photovoltaic (PV) dan Sistem Penyimpanan Energi Baterai (SPEB) di Indonesia dengan beberapa pabrikan manufaktur PV dan baterai (OEM/Original Equipment Manufacturer) pada Kamis (16/3).

Beberapa pabrikan tersebut termasuk PT Utomo Juragan Atap Surya Indonesia, LONGi Solar Technology Co., Ltd, Jiangsu Seraphim Solar System Co., Ltd, Znshine PV-Tech Co., Ltd, Sungrow Power Supply Co., Ltd, PT Huawei Tech Investment, dan REPT BATTERO Energy Co.,Ltd.

Baca Juga: **Menteri ESDM Tegaskan Tak Ada Penyesuaian Harga Gas Khusus untuk 7 Sektor Industri**

“Saat ini kami sedang fokus bekerja sama erat dengan supplier solar PV untuk mendetailkan rencana pembangunan rantai pasok industri panel surya nasional sesuai dengan harapan pemerintah,” ujar Dharma.

Adaro bukan satu-satunya perusahaan batubara yang melirik sektor energi terbarukan. PT Indika Energy Tbk (INDY) juga merancang sejumlah rencana proyek pembangkitan energi surya pada tahun 2023 melalui anak usahanya, Empat Mitra Indika Tenaga Surya (EMITS).

Mayoritas adalah proyek-proyek energi surya di luar Pulau Jawa, antara lain yaitu proyek Sampoerna Kayoe di Maluku dengan kapasitas energi surya sebesar 12.000 kWp dan potensial kapasitas 10,1 mwp + 8,9 Mwh BESS, lalu proyek energi surya untuk PLN, Interport, Petrosea, juga untuk industri tekstil dan rokok.

Target manajemen, EMITS bisa memperoleh kontrak pemasangan sebesar 80 Megawatt peak (MWp) sampai 100 MWp di tahun 2023.

PT TBS Energi Utama Tbk juga tidak ketinggalan mengail peluang bisnis dari sektor EBT. Emiten berkode saham “TOBA” tersebut mengincar target komposisi pendapatan 50% dari energi bersih pada 5-6 tahun ke depan.

Dalam acara Hotel Fairmont selepas acara Saratoga Investment Summit, Kamis (26/1), Wakil Direktur Utama TOBA, Pandu Patria Sjahrir menyampaikan bahwa pihaknya tengah membidik 3-4 proyek pengembangan pembangkit EBT. Ia tidak merinci proyek-proyek mana saja yang dimaksud.

Baca Juga: **Pertamina Geothermal (PGEO) Tingkatkan Kapasitas Produksi Hingga 1.272 MW**

Sebelumnya, TOBA telah memiliki proyek EBT berjalan. Kontan.co.id mencatat, TOBA tengah mengembangkan proyek mini hydro (PL...) berkapasitas 2x3 MW yang berlokasi di Sungai Way Besar, Kecar... Sumber Jaya, Provinsi Lampung.

PT Adimitra Energi Hidro yaitu entitas asosiasi dengan kepemilikan... langsung sebesar 49% (data laporan keuangan interim TOBA per 30... September 2022), telah menandatangani Power Purchase Agreeme... dengan PT PLN pada 2021.

Berdasarkan kesepakatan dalam PPA dengan PLN, Commercial Operation ...ate (COD) direncanakan pada Juni 2024. Selain membangun pembangkit, ...A juga berencana akan mengakuisisi perusahaan pengembang energi

sih ataupun proyek pembangkitnya.

Baca Juga: **Adaro Green, Medco Power, dan Energi Baru TBS Kerjasama di Bisnis Rantai Pasok PLTS**

Direktur Eksekutif Institute for Essential Services Reform (IESR), Fabby Tumiwa mengatakan, ambisi Pemerintah Singapura untuk memacu bauran EBT hingga 3 GW dalam pasokan listrik nasionalnya di 2035 membuka kesempatan bagi para pengembang energi Indonesia untuk memasok kebutuhan tersebut.

“Dengan adanya dua kesempatan ini, pelaku usaha berusaha untuk memenuhi permintaan/kesempatan yang ada,” kata Fabby saat dihubungi Kontan.co.id (19/3).

Lebih lanjut, Fabby menambahkan bahwa peluang untuk memasok listrik ke Singapura menciptakan kesempatan serta permintaan untuk mendorong pertumbuhan industri hilir dan hulu.

“Saya menilai, model yang dikembangkan pemerintah Indonesia via Kemenko Marves bekerja sama dengan pemerintah Singapura adalah sesuatu terobosan. Di sini ada *technology provider* yaitu produsen sel dan modul surya tier-1, komponen PLTS, dan energy storage, dan bekerja sama langsung dengan pengembang PLTS,” kata Fabby.
